1 Stochastic Processes

1.1 Probability Spaces and Random Variables

In this section we recall the basic vocabulary and results of probability theory. A probability space associated with a random experiment is a triple \((\Omega, \mathcal{F}, P)\) where:

(i) \(\Omega\) is the set of all possible outcomes of the random experiment, and it is called the sample space.

(ii) \(\mathcal{F}\) is a family of subsets of \(\Omega\) which has the structure of a \(\sigma\)-field:

a) \(\emptyset \in \mathcal{F}\)

b) If \(A \in \mathcal{F}\), then its complement \(A^c\) also belongs to \(\mathcal{F}\)

c) \(A_1, A_2, \ldots \in \mathcal{F} \implies \bigcup_{i=1}^{\infty} A_i \in \mathcal{F}\)

(iii) \(P\) is a function which associates a number \(P(A)\) to each set \(A \in \mathcal{F}\) with the following properties:

a) \(0 \leq P(A) \leq 1\),

b) \(P(\Omega) = 1\)

\( \quad \) c) For any sequence \(A_1, A_2, \ldots\) of disjoints sets in \(\mathcal{F}\) (that is, \(A_i \cap A_j = \emptyset\) if \(i \neq j\)),

\[ P \left( \bigcup_{i=1}^{\infty} A_i \right) = \sum_{i=1}^{\infty} P(A_i) \]

The elements of the \(\sigma\)-field \(\mathcal{F}\) are called events and the mapping \(P\) is called a probability measure. In this way we have the following interpretation of this model:

\[ P(F) = \text{“probability that the event } F \text{ occurs”} \]

The set \(\emptyset\) is called the empty event and it has probability zero. Indeed, the additivity property (iii,c) implies

\[ P(\emptyset) + P(\emptyset) + \cdots = P(\emptyset) \].
The set $\Omega$ is also called the *certain set* and by property (iii,b) it has probability one. Usually, there will be other events $A \subset \Omega$ such that $P(A) = 1$. If a statement holds for all $\omega$ in a set $A$ with $P(A) = 1$, then it is customary to say that the statement is true *almost surely*, or that the statement holds for almost all $\omega \in \Omega$.

The axioms a), b) and c) lead to the following basic rules of the probability calculus:

\[
P(A \cup B) = P(A) + P(B) \text{ if } A \cap B = \emptyset
\]
\[
P(A^c) = 1 - P(A)
\]
\[
A \subset B \implies P(A) \leq P(B).
\]

**Example 1** Consider the experiment of flipping a coin once.

$\Omega = \{H, T\}$ (the possible outcomes are “Heads” and “Tails”)

$\mathcal{F} = \mathcal{P}(\Omega)$ ($\mathcal{F}$ contains all subsets of $\Omega$)

$P(\{H\}) = P(\{T\}) = \frac{1}{2}$

**Example 2** Consider an experiment that consists of counting the number of traffic accidents at a given intersection during a specified time interval.

$\Omega = \{0, 1, 2, 3, \ldots\}$

$\mathcal{F} = \mathcal{P}(\Omega)$ ($\mathcal{F}$ contains all subsets of $\Omega$)

$P(\{k\}) = e^{-\lambda} \frac{\lambda^k}{k!}$ (Poisson probability with parameter $\lambda > 0$)

Given an arbitrary family $\mathcal{U}$ of subsets of $\Omega$, the smallest $\sigma$-field containing $\mathcal{U}$ is, by definition,

$\sigma(\mathcal{U}) = \cap \{\mathcal{G}, \mathcal{G} \text{ is a } \sigma\text{-field, } \mathcal{U} \subset \mathcal{G}\}$.

The $\sigma$-field $\sigma(\mathcal{U})$ is called the $\sigma$-field generated by $\mathcal{U}$. For instance, the $\sigma$-field generated by the open subsets (or rectangles) of $\mathbb{R}^n$ is called the Borel $\sigma$-field of $\mathbb{R}^n$ and it will be denoted by $\mathcal{B}_{\mathbb{R}^n}$.

**Example 3** Consider a finite partition $\mathcal{P} = \{A_1, \ldots, A_n\}$ of $\Omega$. The $\sigma$-field generated by $\mathcal{P}$ is formed by the unions $A_{i_1} \cup \cdots \cup A_{i_k}$ where $\{i_1, \ldots, i_k\}$ is an arbitrary subset of $\{1, \ldots, n\}$. Thus, the $\sigma$-field $\sigma(\mathcal{P})$ has $2^n$ elements.

**Example 4** We pick a real number at random in the interval $[0, 2]$. $\Omega = [0, 2]$, $\mathcal{F}$ is the Borel $\sigma$-field of $[0, 2]$. The probability of an interval $[a, b] \subset [0, 2]$ is

$P([a, b]) = \frac{b - a}{2}$.

**Example 5** Let an experiment consist of measuring the lifetime of an electric bulb. The sample space $\Omega$ is the set $[0, \infty)$ of nonnegative real numbers. $\mathcal{F}$ is
the Borel σ-field of \([0, \infty)\). The probability that the lifetime is larger than a fixed value \(t \geq 0\) is

\[ P([t, \infty)) = e^{-\lambda t}. \]

A random variable is a mapping

\[ \Omega \xrightarrow{X} \mathbb{R} \]

\[ \omega \rightarrow X(\omega) \]

which is \(\mathcal{F}\)-measurable, that is, \(X^{-1}(B) \in \mathcal{F}\), for any Borel set \(B\) in \(\mathbb{R}\). The random variable \(X\) assigns a value \(X(\omega)\) to each outcome \(\omega\) in \(\Omega\). The measurability condition means that given two real numbers \(a \leq b\), the set of all outcomes \(\omega\) for which \(a \leq X(\omega) \leq b\) is an event. We will denote this event by \(\{a \leq X \leq b\}\) for short, instead of \(\{\omega \in \Omega : a \leq X(\omega) \leq b\}\).

- A random variable defines a σ-field \(\{X^{-1}(B), B \in \mathcal{B}_\mathbb{R}\} \subset \mathcal{F}\) called the σ-field generated by \(X\).
- A random variable defines a probability measure on the Borel σ-field \(\mathcal{B}_\mathbb{R}\) by \(P_X = P \circ X^{-1}\), that is,

\[ P_X(B) = P(X^{-1}(B)) = P(\{\omega : X(\omega) \in B\}). \]

The probability measure \(P_X\) is called the law or the distribution of \(X\).

We will say that a random variable \(X\) has a probability density \(f_X\) if \(f_X(x)\) is a nonnegative function on \(\mathbb{R}\), measurable with respect to the Borel σ-field and such that

\[ P\{a < X < b\} = \int_a^b f_X(x)dx, \]

for all \(a < b\). Notice that \(\int_{-\infty}^{\infty} f_X(x)dx = 1\). Random variables admitting a probability density are called absolutely continuous.

We say that a random variable \(X\) is discrete if it takes a finite or countable number of different values \(x_k\). Discrete random variables do not have densities and their law is characterized by the probability function:

\[ p_k = P(X = x_k). \]

**Example 6** In the experiment of flipping a coin once, the random variable given by

\[ X(H) = 1, X(T) = -1 \]

represents the earning of a player who receives or loses an euro according as the outcome is heads or tails. This random variable is discrete with

\[ P(X = 1) = P(X = -1) = \frac{1}{2}. \]
**Example 7** If \( A \) is an event in a probability space, the random variable
\[
1_A(\omega) = \begin{cases} 
1 & \text{if } \omega \in A \\
0 & \text{if } \omega \notin A
\end{cases}
\]
is called the indicator function of \( A \). Its probability law is called the Bernoulli distribution with parameter \( p = P(A) \).

**Example 8** We say that a random variable \( X \) has the normal law \( N(m, \sigma^2) \) if
\[
P(a < X < b) = \int_a^b \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-m)^2}{2\sigma^2}} dx
\]
for all \( a < b \).

**Example 9** We say that a random variable \( X \) has the binomial law \( B(n, p) \) if
\[
P(X = k) = \binom{n}{k} p^k (1-p)^{n-k},
\]
for \( k = 0, 1, \ldots, n \).

The function \( F_X : \mathbb{R} \to [0, 1] \) defined by
\[
F_X(x) = P(X \leq x) = P_X(\{x \leq x\})
\]
is called the distribution function of the random variable \( X \).

- The distribution function \( F_X \) is non-decreasing, right continuous and with
\[
\lim_{x \to -\infty} F_X(x) = 0, \\
\lim_{x \to +\infty} F_X(x) = 1.
\]
- If the random variable \( X \) is absolutely continuous with density \( f_X \), then,
\[
F_X(x) = \int_{-\infty}^x f_X(y)dy,
\]
and if, in addition, the density is continuous, then \( F_X'(x) = f_X(x) \).

The mathematical expectation (or expected value) of a random variable \( X \) is defined as the integral of \( X \) with respect to the probability measure \( P \):
\[
E(X) = \int_{\Omega} X dP.
\]
In particular, if \( X \) is a discrete variable that takes the values \( \alpha_1, \alpha_2, \ldots \) on the sets \( A_1, A_2, \ldots \), then its expectation will be
\[
E(X) = \alpha_1 P(A_1) + \alpha_2 P(A_2) + \cdots.
\]
Notice that $E(1_A) = P(A)$, so the notion of expectation is an extension of the notion of probability.

If $X$ is a non-negative random variable it is possible to find discrete random variables $X_n$, $n = 1, 2, \ldots$ such that

$$X_1(\omega) \leq X_2(\omega) \leq \cdots$$

and

$$\lim_{n \to \infty} X_n(\omega) = X(\omega)$$

for all $\omega$. Then $E(X) = \lim_{n \to \infty} E(X_n) \leq +\infty$, and this limit exists because the sequence $E(X_n)$ is non-decreasing. If $X$ is an arbitrary random variable, its expectation is defined by

$$E(X) = E(X^+) - E(X^-),$$

where $X^+ = \max(X, 0)$, $X^- = -\min(X, 0)$, provided that both $E(X^+)$ and $E(X^-)$ are finite. Note that this is equivalent to say that $E(|X|) < \infty$, and in this case we will say that $X$ is integrable.

A simple computational formula for the expectation of a non-negative random variable is as follows:

$$E(X) = \int_0^{+\infty} P(X > t) dt.$$

In fact,

$$E(X) = \int_{\Omega} XdP = \int_{\Omega} \left( \int_0^{+\infty} 1_{\{X > t\}} dt \right) dP = \int_0^{+\infty} P(X > t) dt.$$
Example 10 If $X$ is a random variable with normal law $N(0, \sigma^2)$ and $\lambda$ is a real number,

$$E(\exp (\lambda X)) = \frac{1}{\sqrt{2\pi}\sigma^2} \int_{-\infty}^{\infty} e^{\frac{x^2}{2\sigma^2}} dx$$

$$= \frac{1}{\sqrt{2\pi}\sigma^2} e^{\frac{\lambda^2}{2\sigma^2}} \int_{-\infty}^{\infty} e^{-\frac{(x - \sigma^2\lambda)^2}{2\sigma^2}} dx$$

$$= e^{\frac{\lambda^2}{2\sigma^2}}.$$

Example 11 If $X$ is a random variable with Poisson distribution of parameter $\lambda > 0$, then

$$E(X) = \sum_{n=0}^{\infty} \frac{e^{-\lambda} \lambda^n}{n!} = \lambda e^{-\lambda} \sum_{n=1}^{\infty} \frac{e^{-\lambda} \lambda^{n-1}}{(n-1)!} = \lambda.$$

The variance of a random variable $X$ is defined by

$$\sigma_X^2 = \text{Var}(X) = E((X - E(X))^2) = E(X^2) - [E(X)]^2,$$

provided $E(X^2) < \infty$. The variance of $X$ measures the deviation of $X$ from its expected value.

If $X$ and $Y$ are two random variables with $E(X^2) < \infty$ and $E(Y^2) < \infty$, then its covariance is defined by

$$\text{cov}(X, Y) = E[(X - E(X))(Y - E(Y))] = E(XY) - E(X)E(Y).$$

A random variable $X$ is said to have a finite moment of order $p \geq 1$, provided $E(|X|^p) < \infty$. In this case, the $p$th moment of $X$ is defined by

$$m_p = E(X^p).$$

The set of random variables with finite $p$th moment is denoted by $L^p(\Omega, \mathcal{F}, P)$.

The characteristic function of a random variable $X$ is defined by

$$\varphi_X(t) = E(e^{itX}).$$

The moments of a random variable can be computed from the derivatives of the characteristic function at the origin:

$$m_n = \frac{1}{i^n} \varphi_X^{(n)}(0),$$

for $n = 1, 2, 3, \ldots$.

We say that $X = (X_1, \ldots, X_n)$ is an $n$-dimensional random vector if its components are random variables. This is equivalent to say that $X$ is a random variable with values in $\mathbb{R}^n$. 

The mathematical expectation of an $n$-dimensional random vector $X$ is, by definition, the vector

$$E(X) = (E(X_1), \ldots, E(X_n))$$

The covariance matrix of an $n$-dimensional random vector $X$ is, by definition, the matrix $\Gamma_X = (\text{cov}(X_i, X_j))_{1 \leq i, j \leq n}$. This matrix is clearly symmetric. Moreover, it is non-negative definite, that means,

$$\sum_{i,j=1}^{n} \Gamma_X(i,j)a_i a_j \geq 0$$

for all real numbers $a_1, \ldots, a_n$. Indeed,

$$\sum_{i,j=1}^{n} \Gamma_X(i,j)a_i a_j = \sum_{i,j=1}^{n} a_i a_j \text{cov}(X_i, X_j) = \text{Var}(\sum_{i=1}^{n} a_i X_i) \geq 0$$

As in the case of real-valued random variables we introduce the law or distribution of an $n$-dimensional random vector $X$ as the probability measure defined on the Borel $\sigma$-field of $\mathbb{R}^n$ by

$$P_X(B) = P(X^{-1}(B)) = P(X \in B).$$

We will say that a random vector $X$ has a probability density $f_X$ if $f_X(x)$ is a nonnegative function on $\mathbb{R}^n$, measurable with respect to the Borel $\sigma$-field and such that

$$P \{a_i < X_i < b_i, i = 1, \ldots, n\} = \int_{a_n}^{b_n} \cdots \int_{a_1}^{b_1} f_X(x_1, \ldots, x_n) dx_1 \cdots dx_n,$$

for all $a_i < b_i$. Notice that

$$\int_{-\infty}^{+\infty} \cdots \int_{-\infty}^{+\infty} f_X(x_1, \ldots, x_n) dx_1 \cdots dx_n = 1.$$

We say that an $n$-dimensional random vector $X$ has a multidimensional normal law $N(m, \Gamma)$, where $m \in \mathbb{R}^n$, and $\Gamma$ is a symmetric positive definite matrix, if $X$ has the density function

$$f_X(x_1, \ldots, x_n) = (2\pi \det \Gamma)^{-\frac{n}{2}} e^{-\frac{1}{2} \sum_{i,j=1}^{n}(x_i - m_i)(x_j - m_j)\Gamma_{ij}^{-1}}.$$

In that case, we have, $m = E(X)$ and $\Gamma = \Gamma_X$.

If the matrix $\Gamma$ is diagonal

$$\Gamma = \begin{pmatrix} \sigma_1^2 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sigma_n^2 \end{pmatrix}$$
then the density of $X$ is the product of $n$ one-dimensional normal densities:

$$f_X(x_1, \ldots, x_n) = \prod_{i=1}^{n} \left( \frac{1}{\sqrt{2\pi \sigma_i^2}} e^{-\frac{(x_i-m_i)^2}{2\sigma_i^2}} \right).$$

There exists degenerate normal distributions which have a singular covariance matrix $\Gamma$. These distributions do not have densities and the law of a random variable $X$ with a (possibly degenerated) normal law $N(m, \Gamma)$ is determined by its characteristic function:

$$E(e^{it'X}) = \exp \left( it'm - \frac{1}{2} t'\Gamma t \right),$$

where $t \in \mathbb{R}^n$. In this formula $t'$ denotes a row vector ($1 \times n$ matrix) and $t$ denoted a column vector ($n \times 1$ matrix).

If $X$ is an $n$-dimensional normal vector with law $N(m, \Gamma)$ and $A$ is a matrix of order $m \times n$, then $AX$ is an $m$-dimensional normal vector with law $N(Am, A\Gamma A')$.

We recall some basic inequalities of probability theory:

- **Chebyshev’s inequality**: If $\lambda > 0$

  $$P(|X| > \lambda) \leq \frac{1}{\lambda^p} E(|X|^p).$$

- **Schwartz’s inequality**:

  $$E(XY) \leq \sqrt{E(X^2)E(Y^2)}.$$

- **Hölder’s inequality**:

  $$E(XY) \leq [E(|X|^p)]^{\frac{1}{p}} [E(|Y|^q)]^{\frac{1}{q}},$$

  where $p, q > 1$ and $\frac{1}{p} + \frac{1}{q} = 1$.

- **Jensen’s inequality**: If $\varphi : \mathbb{R} \to \mathbb{R}$ is a convex function such that the random variables $X$ and $\varphi(X)$ have finite expectation, then,

  $$\varphi(E(X)) \leq E(\varphi(X)).$$

  In particular, for $\varphi(x) = |x|^p$, with $p \geq 1$, we obtain

  $$|E(X)|^p \leq E(|X|^p).$$

We recall the different types of convergence for a sequence of random variables $X_n$, $n = 1, 2, 3, \ldots$:
Almost sure convergence: $X_n \xrightarrow{a.s.} X$, if
\[
\lim_{n \to \infty} X_n(\omega) = X(\omega),
\]
for all $\omega \notin N$, where $P(N) = 0$.

Convergence in probability: $X_n \xrightarrow{P} X$, if
\[
\lim_{n \to \infty} P(|X_n - X| > \varepsilon) = 0,
\]
for all $\varepsilon > 0$.

Convergence in mean of order $p \geq 1$: $X_n \xrightarrow{L^p} X$, if
\[
\lim_{n \to \infty} E(|X_n - X|^p) = 0.
\]

Convergence in law: $X_n \xrightarrow{\mathcal{L}} X$, if
\[
\lim_{n \to \infty} F_{X_n}(x) = F_X(x),
\]
for any point $x$ where the distribution function $F_X$ is continuous.

- The convergence in mean of order $p$ implies the convergence in probability. Indeed, applying Chebyshev’s inequality yields
\[
P(|X_n - X| > \varepsilon) \leq \frac{1}{\varepsilon^p} E(|X_n - X|^p).
\]

- The almost sure convergence implies the convergence in probability. Conversely, the convergence in probability implies the existence of a subsequence which converges almost surely.

- The almost sure convergence implies the convergence in mean of order $p \geq 1$, if the random variables $X_n$ are bounded in absolute value by a fixed nonnegative random variable $Y$ possessing $p$th finite moment (dominated convergence theorem):
\[
|X_n| \leq Y, \quad E(Y^p) < \infty.
\]

- The convergence in probability implies the convergence law, the reciprocal being also true when the limit is constant.

The independence is a basic notion in probability theory. Two events $A, B \in \mathcal{F}$ are said independent provided
\[
P(A \cap B) = P(A)P(B).
\]
Given an arbitrary collection of events \( \{A_i, i \in I\} \), we say that the events of the collection are independent provided

\[
P(A_{i_1} \cap \cdots \cap A_{i_k}) = P(A_{i_1}) \cdots P(A_{i_k})
\]

for every finite subset of indexes \( \{i_1, \ldots, i_k\} \subset I \).

A collection of classes of events \( \{\mathcal{G}_i, i \in I\} \) is independent if any collection of events \( \{A_i, i \in I\} \) such that \( A_i \in \mathcal{G}_i \) for all \( i \in I \), is independent.

A collection of random variables \( \{X_i, i \in I\} \) is independent if the collection of \( \sigma \)-fields \( \{X_i^{-1}(B_R^n), i \in I\} \) is independent. This means that

\[
P(X_{i_1} \in B_{i_1}, \ldots, X_{i_k} \in B_{i_k}) = P(X_{i_1} \in B_{i_1}) \cdots P(X_{i_k} \in B_{i_k}),
\]

for every finite set of indexes \( \{i_1, \ldots, i_k\} \subset I \), and for all Borel sets \( B_j \).

Suppose that \( X, Y \) are two independent random variables with finite expectation. Then the product \( XY \) has also finite expectation and

\[
E(XY) = E(X)E(Y).
\]

More generally, if \( X_1, \ldots, X_n \) are independent random variables,

\[
E[g_1(X_1) \cdots g_n(X_n)] = E[g_1(X_1)] \cdots E[g_n(X_n)],
\]

where \( g_i \) are measurable functions such that \( E[|g_i(X_i)|] < \infty \).

The components of a random vector are independent if and only if the density or the probability function of the random vector is equal to the product of the marginal densities, or probability functions.

The conditional probability of an event \( A \) given another event \( B \) such that \( P(B) > 0 \) is defined by

\[
P(A|B) = \frac{P(A \cap B)}{P(B)}.
\]

We see that \( A \) and \( B \) are independent if and only if \( P(A|B) = P(A) \). The conditional probability \( P(A|B) \) represents the probability of the event \( A \) modified by the additional information that the event \( B \) has occurred. The mapping

\[
A \mapsto P(A|B)
\]

defines a new probability on the \( \sigma \)-field \( \mathcal{F} \) concentrated on the set \( B \). The mathematical expectation of an integrable random variable \( X \) with respect to this new probability will be the conditional expectation of \( X \) given \( B \) and it can be computed as follows:

\[
E(X|B) = \frac{1}{P(B)}E(X1_B).
\]

The following are two main limit theorems in probability theory.
Theorem 1 (Law of Large Numbers) Let \( \{X_n, n \geq 1\} \) be a sequence of independent, identically distributed random variables, such that \( E(|X_1|) < \infty \). Then,
\[
\frac{X_1 + \cdots + X_n}{n} \xrightarrow{a.s.} m,
\]
where \( m = E(X_1) \).

Theorem 2 (Central Limit Theorem) Let \( \{X_n, n \geq 1\} \) be a sequence of independent, identically distributed random variables, such that \( E(X_1^2) < \infty \). Set \( m = E(X_1) \) and \( \sigma^2 = \text{Var}(X_1) \). Then,
\[
\frac{X_1 + \cdots + X_n - nm}{\sigma \sqrt{n}} \xrightarrow{d} N(0, 1).
\]

1.2 Stochastic Processes: Definitions and Examples

A stochastic process with state space \( S \) is a collection of random variables \( \{X_t, t \in T\} \) defined on the same probability space \( (\Omega, F, P) \). The set \( T \) is called its parameter set. If \( T = \mathbb{N} = \{0, 1, 2, \ldots\} \), the process is said to be a discrete parameter process. If \( T \) is not countable, the process is said to have a continuous parameter. In the latter case the usual examples are \( T = \mathbb{R}_+ = [0, \infty) \) and \( T = [a, b] \subset \mathbb{R} \). The index \( t \) represents time, and then one thinks of \( X_t \) as the “state” or the “position” of the process at time \( t \). The state space is \( \mathbb{R} \) in most usual examples, and then the process is said real-valued. There will be also examples where \( S \) is \( \mathbb{N} \), the set of all integers, or a finite set.

For every fixed \( \omega \in \Omega \), the mapping
\[
(t \mapsto X_t(\omega))
\]
defined on the parameter set \( T \), is called a realization, trajectory, sample path or sample function of the process.

Let \( \{X_t, t \in T\} \) be a real-valued stochastic process and \( \{t_1 < \cdots < t_n\} \subset T \), then the probability distribution \( P_{t_1, \ldots, t_n} = P \circ (X_{t_1}, \ldots, X_{t_n})^{-1} \) of the random vector
\[
(X_{t_1}, \ldots, X_{t_n}) : \Omega \longrightarrow \mathbb{R}^n.
\]
is called a finite-dimensional marginal distribution of the process \( \{X_t, t \in T\} \).

The following theorem, due to Kolmogorov, establishes the existence of a stochastic process associated with a given family of finite-dimensional distributions satisfying the consistence condition:

Theorem 3 Consider a family of probability measures
\[
\{P_{t_1, \ldots, t_n}, \ t_1 < \cdots < t_n, n \geq 1, t_i \in T\}
\]
such that:

1. \( P_{t_1, \ldots, t_n} \) is a probability on \( \mathbb{R}^n \)
2. (Consistence condition): If \( \{t_{k_1} < \cdots < t_{k_m}\} \subset \{t_1 < \cdots < t_n\} \), then \( P_{t_{k_1}, \ldots, t_{k_m}} \) is the marginal of \( P_{t_1, \ldots, t_n} \), corresponding to the indexes \( k_1, \ldots, k_m \).

Then, there exists a real-valued stochastic process \( \{X_t, t \geq 0\} \) defined in some probability space \( (\Omega, \mathcal{F}, P) \) which has the family \( \{P_{t_1, \ldots, t_n}\} \) as finite-dimensional marginal distributions.

A real-valued process \( \{X_t, t \geq 0\} \) is called a second order process provided \( E(X_t^2) < \infty \) for all \( t \in T \). The mean and the covariance function of a second order process \( \{X_t, t \geq 0\} \) are defined by

\[
\begin{align*}
    m_X(t) &= E(X_t) \\
    \Gamma_X(s, t) &= \text{Cov}(X_s, X_t) = E((X_s - m_X(s))(X_t - m_X(t))).
\end{align*}
\]

The variance of the process \( \{X_t, t \geq 0\} \) is defined by

\[
\sigma^2_X(t) = \Gamma_X(t, t) = \text{Var}(X_t).
\]

**Example 12** Let \( X \) and \( Y \) be independent random variables. Consider the stochastic process with parameter \( t \in [0, \infty) \)

\[
    X_t = tX + Y.
\]

The sample paths of this process are lines with random coefficients. The finite-dimensional marginal distributions are given by

\[
P(X_{t_1} \leq x_1, \ldots, X_{t_n} \leq x_n) = \int_{\mathbb{R}} F_X\left( \min_{1 \leq i \leq n} \frac{x_i - y}{t_i} \right) P_Y(dy).
\]

**Example 13** Consider the stochastic process

\[
    X_t = A \cos(\phi + \lambda t),
\]

where \( A \) and \( \phi \) are independent random variables such that \( E(A) = 0, E(A^2) < \infty \) and \( \phi \) is uniformly distributed on \([0, 2\pi]\). This is a second order process with

\[
\begin{align*}
    m_X(t) &= 0 \\
    \Gamma_X(s, t) &= \frac{1}{2} E(A^2) \cos(\lambda(t - s)).
\end{align*}
\]

**Example 14** *Arrival process:* Consider the process of arrivals of customers at a store, and suppose the experiment is set up to measure the interarrival times. Suppose that the interarrival times are positive random variables \( X_1, X_2, \ldots \). Then, for each \( t \in [0, \infty) \), we put \( N_t = k \) if and only if the integer \( k \) is such that

\[
    X_1 + \cdots + X_k \leq t < X_1 + \cdots + X_{k+1}.
\]
and we put $N_t = 0$ if $t < X_1$. Then $N_t$ is the number of arrivals in the time interval $[0, t]$. Notice that for each $t \geq 0$, $N_t$ is a random variable taking values in the set $S = \mathbb{N}$. Thus, \{$N_t, t \geq 0\}$ is a continuous time process with values in the state space $\mathbb{N}$. The sample paths of this process are non-decreasing, right continuous and they increase by jumps of size 1 at the points $X_1 + \cdots + X_k$.

On the other hand, $N_t < \infty$ for all $t \geq 0$ if and only if
\[
\sum_{k=1}^{\infty} X_k = \infty.
\]

**Example 15** Consider a discrete time stochastic process \{$X_n, n = 0, 1, 2, \ldots\$} with a finite number of states $S = \{1, 2, 3\}$. The dynamics of the process is as follows. You move from state 1 to state 2 with probability 1. From state 3 you move either to 1 or to 2 with equal probability 1/2, and from 2 you jump to 3 with probability 1/3, otherwise stay at 2. This is an example of a Markov chain.

A real-valued stochastic process \{$X_t, t \in T\$} is said to be Gaussian or normal if its finite-dimensional marginal distributions are multi-dimensional Gaussian laws. The mean $m_X(t)$ and the covariance function $\Gamma_X(s, t)$ of a Gaussian process determine its finite-dimensional marginal distributions. Conversely, suppose that we are given an arbitrary function $m : T \to \mathbb{R}$, and a symmetric function $\Gamma : T \times T \to \mathbb{R}$, which is nonnegative definite, that is
\[
\sum_{i, j=1}^{n} \Gamma(t_i, t_j) a_i a_j \geq 0
\]
for all $t_i \in T$, $a_i \in \mathbb{R}$, and $n \geq 1$. Then there exists a Gaussian process with mean $m$ and covariance function $\Gamma$.

**Example 16** Let $X$ and $Y$ be random variables with joint Gaussian distribution. Then the process $X_t = tX + Y$, $t \geq 0$, is Gaussian with mean and covariance functions
\[
m_X(t) = tE(X) + E(Y), \\
\Gamma_X(s, t) = t^2\text{Var}(X) + 2t\text{Cov}(X, Y) + \text{Var}(Y).
\]

**Example 17** Gaussian white noise: Consider a stochastic process \{$X_t, t \in T\$} such that the random variables $X_t$ are independent and with the same law $N(0, \sigma^2)$. Then, this process is Gaussian with mean and covariance functions
\[
m_X(t) = 0 \\
\Gamma_X(s, t) = \begin{cases} 
1 & \text{if } s = t \\
0 & \text{if } s \neq t
\end{cases}
\]

**Definition 4** A stochastic process \{$X_t, t \in T\$} is equivalent to another stochastic process \{$Y_t, t \in T\$} if for each $t \in T$
\[
P\{X_t = Y_t\} = 1.
\]
We also say that \( \{X_t, t \in T\} \) is a version of \( \{Y_t, t \in T\} \). Two equivalent processes may have quite different sample paths.

**Example 18** Let \( \xi \) be a nonnegative random variable with continuous distribution function. Set \( T = [0, \infty) \). The processes

\[
X_t = 0 \\
Y_t = \begin{cases} 
0 & \text{if } \xi \neq t \\
1 & \text{if } \xi = t
\end{cases}
\]

are equivalent but their sample paths are different.

**Definition 5** Two stochastic processes \( \{X_t, t \in T\} \) and \( \{Y_t, t \in T\} \) are said to be indistinguishable if \( X(\omega) = Y(\omega) \) for all \( \omega \notin N \), with \( P(N) = 0 \).

Two stochastic process which have right continuous sample paths and are equivalent, then they are indistinguishable.

Two discrete time stochastic processes which are equivalent, they are also indistinguishable.

**Definition 6** A real-valued stochastic process \( \{X_t, t \in T\} \), where \( T \) is an interval of \( \mathbb{R} \), is said to be continuous in probability if, for any \( \varepsilon > 0 \) and every \( t \in T \)

\[
\lim_{s \to t} P(|X_t - X_s| > \varepsilon) = 0.
\]

**Definition 7** Fix \( p \geq 1 \). Let \( \{X_t, t \in T\} \) be a real-valued stochastic process, where \( T \) is an interval of \( \mathbb{R} \), such that \( E(|X_t|^p) < \infty \), for all \( t \in T \). The process \( \{X_t, t \geq 0\} \) is said to be continuous in mean of order \( p \) if

\[
\lim_{s \to t} E(|X_t - X_s|^p) = 0.
\]

Continuity in mean of order \( p \) implies continuity in probability. However, the continuity in probability (or in mean of order \( p \)) does not necessarily implies that the sample paths of the process are continuous.

In order to show that a given stochastic process have continuous sample paths it is enough to have suitable estimations on the moments of the increments of the process. The following continuity criterion by Kolmogorov provides a sufficient condition of this type:

**Proposition 8 (Kolmogorov continuity criterion)** Let \( \{X_t, t \in T\} \) be a real-valued stochastic process and \( T \) is a finite interval. Suppose that there exist constants \( \alpha > 1 \) and \( \beta > 0 \) such that

\[
E(|X_t - X_s|^{\alpha}) \leq c_T|t - s|^{1+\beta}
\]

for all \( s, t \in T \). Then, there exists a version of the process \( \{X_t, t \in T\} \) with continuous sample paths. Moreover for any \( \gamma < \frac{\beta}{\alpha} \), the trajectories of this version are Hölder continuous of order \( \gamma \), that is

\[
|X_t(\omega) - X_s(\omega)| \leq G_{\gamma}(\omega)|t - s|^\gamma,
\]

for some random variable \( G_{\gamma} \).
1.3 The Poisson Process

A random variable $T : \Omega \rightarrow (0, \infty)$ has exponential distribution of parameter $\lambda > 0$ if

$$P(T > t) = e^{-\lambda t}$$

for all $t \geq 0$. Then $T$ has a density function

$$f_T(t) = \lambda e^{-\lambda t}1_{(0, \infty)}(t).$$

The mean of $T$ is given by $E(T) = \frac{1}{\lambda}$, and its variance is $\text{Var}(T) = \frac{1}{\lambda^2}$. The exponential distribution plays a fundamental role in continuous-time Markov processes because of the following result.

**Proposition 9 (Memoryless property)** A random variable $T : \Omega \rightarrow (0, \infty)$ has an exponential distribution if and only if it has the following memoryless property

$$P(T > s + t | T > s) = P(T > t)$$

for all $s, t \geq 0$.

**Proof.** Suppose first that $T$ has exponential distribution of parameter $\lambda > 0$. Then

$$P(T > s + t | T > s) = \frac{P(T > s + t)}{P(T > s)} = \frac{e^{-\lambda(s+t)}}{e^{-\lambda s}} = e^{-\lambda t} = P(T > t).$$

The converse implication follows from the fact that the function $g(t) = P(T > t)$ satisfies

$$g(s+t) = g(s)g(t),$$

for all $s, t \geq 0$ and $g(0) = 1$. □

A stochastic process $\{N_t, t \geq 0\}$ defined on a probability space $(\Omega, \mathcal{F}, P)$ is said to be a **Poisson process of rate** $\lambda$ if it verifies the following properties:

i) $N_t = 0$,

ii) for any $n \geq 1$ and for any $0 \leq t_1 < \cdots < t_n$ the increments $N_{t_n} - N_{t_{n-1}}, \ldots, N_{t_2} - N_{t_1}$, are independent random variables,

iii) for any $0 \leq s < t$, the increment $N_t - N_s$ has a Poisson distribution with parameter $\lambda(t-s)$, that is,

$$P(N_t - N_s = k) = e^{-\lambda(t-s)}\left[\frac{\lambda(t-s)}{k!}\right]^k,$$

$k = 0, 1, 2, \ldots$, where $\lambda > 0$ is a fixed constant.
Notice that conditions i) to iii) characterize the finite-dimensional marginal distributions of the process \( \{N_t, t \geq 0\} \). Condition ii) means that the Poisson process has independent and stationary increments.

A concrete construction of a Poisson process can be done as follows. Consider a sequence \( \{X_n, n \geq 1\} \) of independent random variables with exponential law of parameter \( \lambda \). Set \( T_0 = 0 \) and for \( n \geq 1, T_n = X_1 + \cdots + X_n \). Notice that \( \lim_{n \to \infty} T_n = \infty \) almost surely, because by the strong law of large numbers

\[
\lim_{n \to \infty} \frac{T_n}{n} = \frac{1}{\lambda}.
\]

Let \( \{N_t, t \geq 0\} \) be the arrival process associated with the interarrival times \( X_n \). That is

\[
N_t = \sum_{n=1}^{\infty} n \mathbf{1}_{\{T_n \leq t < T_{n+1}\}}.
\] (2)

**Proposition 10** The stochastic process \( \{N_t, t \geq 0\} \) defined in (2) is a Poisson process with parameter \( \lambda > 0 \).

**Proof.** Clearly \( N_0 = 0 \). We first show that \( N_t \) has a Poisson distribution with parameter \( \lambda t \). We have

\[
P(N_t = n) = P(T_n \leq t < T_{n+1}) = P(T_n \leq t < T_n + X_{n+1})
\]

\[
= \int_{\{x \leq t < x+y\}} f_{T_n}(x) \lambda e^{-\lambda y} dx dy
\]

\[
= \int_0^t f_{T_n}(x) e^{-\lambda (t-x)} dx.
\]

The random variable \( T_n \) has a gamma distribution \( \Gamma(n, \lambda) \) with density

\[
f_{T_n}(x) = \frac{\lambda^n}{(n-1)!} x^{n-1} e^{-\lambda x} \mathbf{1}_{(0,\infty)}(x).
\]

Hence,

\[
P(N_t = n) = e^{-\lambda t} \frac{(\lambda t)^n}{n!}.
\]

Now we will show that \( N_{t+s} - N_s \) is independent of the random variables \( \{N_r, r \leq s\} \) and it has a Poisson distribution of parameter \( \lambda t \). Consider the event

\[
\{N_s = k\} = \{T_k \leq s < T_{k+1}\},
\]

where \( 0 \leq s < t \) and \( 0 \leq k \). On this event the interarrival times of the process \( \{N_t - N_s, t \geq s\} \) are

\[
\widetilde{X}_1 = X_{k+1} - (s - T_k) = T_{k+1} - s
\]

and

\[
\widetilde{X}_n = X_{k+n}
\]

16
for \( n \geq 2 \). Then, conditional on \( \{N_s = k\} \) and on the values of the random variables \( X_1, \ldots, X_k \), due to the memoryless property of the exponential law and independence of the \( X_n \), the interarrival times \( \{\tilde{X}_n, n \geq 1\} \) are independent and with exponential distribution of parameter \( \lambda \). Hence, \( \{N_{t+s} - N_s, t \geq 0\} \) has the same distribution as \( \{N_t, t \geq 0\} \), and it is independent of \( \{N_r, r \leq s\} \).

Notice that \( E(N_t) = \lambda t \). Thus \( \lambda \) is the expected number of arrivals in an interval of unit length, or in other words, \( \lambda \) is the arrival rate. On the other hand, the expect time until a new arrival is \( \frac{1}{\lambda} \). Finally, \( \text{Var}(N_t) = \lambda t \).

We have seen that the sample paths of the Poisson process are discontinuous with jumps of size 1. However, the Poisson process is continuous in mean of order 2:

\[
E \left[ (N_t - N_s)^2 \right] = \lambda (t - s) + \left| \lambda(t - s) \right|^2 \xrightarrow{t \to 0} 0.
\]

Notice that we cannot apply here the Kolmogorov continuity criterion.

The Poisson process with rate \( \lambda > 0 \) can also be characterized as an integer-valued process, starting from 0, with non-decreasing paths, with independent increments, and such that, as \( h \downarrow 0 \), uniformly in \( t \),

\[
P(X_{t+h} - X_t = 0) = 1 - \lambda h + o(h),
\]

\[
P(X_{t+h} - X_t = 1) = \lambda h + o(h).
\]

**Example 19** An item has a random lifetime whose distribution is exponential with parameter \( \lambda = 0.0002 \) (time is measured in hours). The expected lifetime of an item is \( \frac{1}{\lambda} = 5000 \) hours, and the variance is \( \frac{1}{\lambda^2} = 25 \times 10^6 \) hours\(^2\). When it fails, it is immediately replaced by an identical item; etc. If \( N_t \) is the number of failures in \([0, t]\), we may conclude that the process of failures \( \{N_t, t \geq 0\} \) is a Poisson process with rate \( \lambda > 0 \).

Suppose that the cost of a replacement is \( \beta \) euros, and suppose that the discount rate of money is \( \alpha > 0 \). So, the present value of all future replacement costs is

\[
C = \sum_{n=1}^{\infty} \beta e^{-\alpha T_n}.
\]

Its expected value will be

\[
E(C) = \sum_{n=1}^{\infty} \beta E(e^{-\alpha T_n}) = \frac{\beta \lambda}{\alpha}.
\]

For \( \beta = 800, \alpha = 0.24/(365 \times 24) \) we obtain \( E(C) = 5840 \) euros.

The following result is an interesting relation between the Poisson processes and uniform distributions. This result say that the jumps of a Poisson process are as randomly distributed as possible.
**Proposition 11** Let \( \{N_t, t \geq 0\} \) be a Poisson process. Then, conditional on \( \{N_t, t \geq 0\} \) having exactly \( n \) jumps in the interval \([s, s+t]\), the times at which jumps occur are uniformly and independently distributed on \([s, s+t]\).

**Proof.** We will show this result only for \( n = 1 \). By stationarity of increments, it suffices to consider the case \( s = 0 \). Then, for \( 0 \leq u \leq t \)

\[
P(T_1 \leq u | N_t = 1) = \frac{P(T_1 \leq u \cap \{N_t = 1\})}{P(N_t = 1)}
\]

\[
= \frac{P(\{N_u = 1\} \cap \{N_t - N_u = 0\})}{P(N_t = 1)}
\]

\[
= \frac{\lambda u e^{-\lambda u} - \lambda(t-u)e^{-\lambda t}}{\lambda te^{-\lambda t}} = \frac{u}{t}.
\]

**Exercises**

1.1 Consider a random variable \( X \) taking the values \(-2, 0, 2\) with probabilities 0.4, 0.3, 0.3 respectively. Compute the expected values of \( X, 3X^2 + 5, e^{-X} \).

1.2 The headway \( X \) between two vehicles at a fixed instant is a random variable with

\[
P(X \leq t) = 1 - 0.6 e^{-0.02t} - 0.4 e^{-0.03t},
\]

\( t \geq 0 \). Find the expected value and the variance of the headway.

1.3 Let \( Z \) be a random variable with law \( N(0, \sigma^2) \). From the expression

\[
E(e^{\lambda Z}) = e^{\frac{1}{2} \lambda^2 \sigma^2},
\]

deduce the following formulas for the moments of \( Z \):

\[
E(Z^{2k}) = \frac{(2k)!}{2^k k!} \sigma^{2k},
\]

\[
E(Z^{2k-1}) = 0.
\]

1.4 Let \( Z \) be a random variable with Poisson distribution with parameter \( \lambda \). Show that the characteristic function of \( Z \) is

\[
\phi_Z(t) = \exp \left[ \lambda (e^{it} - 1) \right].
\]

As an application compute \( E(Z^2), \Var(Z) \) and \( E(Z^3) \).

1.5 Let \( \{Y_n, n \geq 1\} \) be independent and identically distributed non-negative random variables. Put \( Z_0 = 0 \), and \( Z_n = Y_1 + \cdots + Y_n \) for \( n \geq 1 \). We think of \( Z_n \) as the time of the \( n \)th arrival into a store. The stochastic process \( \{Z_n, n \geq 0\} \) is called a renewal process. Let \( N_t \) be the number of arrivals during \((0,t]\).
a) Show that \( P(N_t \geq n) = P(Z_n \leq t) \), for all \( n \geq 1 \) and \( t \geq 0 \).

b) Show that for almost all \( \omega \), \( \lim_{t \to \infty} N_t(\omega) = \infty \).

c) Show that almost surely \( \lim_{t \to \infty} \frac{N_t}{t} = a \), where \( a = E(Y_1) \).

d) Using the inequalities \( Z_{N_t} \leq t < Z_{N_t+1} \) show that almost surely

\[
\lim_{t \to \infty} \frac{N_t}{t} = \frac{1}{a}.
\]

1.6 Let \( X \) and \( U \) be independent random variables, \( U \) is uniform in \([0, 2\pi]\), and the probability density of \( X \) is for \( x > 0 \)

\[
f_X(x) = 2x^3e^{-1/2x^4}.
\]

Show that the process

\[
X_t = X^2 \cos(2\pi t + U)
\]

is Gaussian and compute its mean and covariance functions.

2 Martingales

We will first introduce the notion of conditional expectation of a random variable \( X \) with respect to a \( \sigma \)-field \( \mathcal{B} \subset \mathcal{F} \) in a probability space \((\Omega, \mathcal{F}, P)\).

2.1 Conditional Expectation

Consider an integrable random variable \( X \) defined in a probability space \((\Omega, \mathcal{F}, P)\), and a \( \sigma \)-field \( \mathcal{B} \subset \mathcal{F} \). We define the conditional expectation of \( X \) given \( \mathcal{B} \) (denoted by \( E(X|\mathcal{B}) \)) to be any integrable random variable \( Z \) that verifies the following two properties:

(i) \( Z \) is measurable with respect to \( \mathcal{B} \).

(ii) For all \( A \in \mathcal{B} \)

\[
E(Z1_A) = E(X1_A).
\]

It can be proved that there exists a unique (up to modifications on sets of probability zero) random variable satisfying these properties. That is, if \( \tilde{Z} \) and \( Z \) verify the above properties, then \( Z = \tilde{Z} \), \( P \)-almost surely.

Property (ii) implies that for any bounded and \( \mathcal{B} \)-measurable random variable \( Y \) we have

\[
E(E(X|\mathcal{B})Y) = E(XY).
\]

Example 1 Consider the particular case where the \( \sigma \)-field \( \mathcal{B} \) is generated by a finite partition \( \{B_1, ..., B_m\} \). In this case, the conditional expectation \( E(X|\mathcal{B}) \)
is a discrete random variable that takes the constant value \( E(X|B_j) \) on each set \( B_j \):

\[
E(X|B) = \sum_{j=1}^{m} \frac{E(X 1_{B_j})}{P(B_j)} 1_{B_j}.
\]

Here are some rules for the computation of conditional expectations in the general case:

**Rule 1** The conditional expectation is lineal:

\[
E(aX + bY|B) = aE(X|B) + bE(Y|B)
\]

**Rule 2** A random variable and its conditional expectation have the same expectation:

\[
E(E(X|B)) = E(X)
\]

This follows from property (ii) taking \( A = \Omega \).

**Rule 3** If \( X \) and \( B \) are independent, then \( E(X|B) = E(X) \).

In fact, the constant \( E(X) \) is clearly \( B \)-measurable, and for all \( A \in B \) we have

\[
E(X 1_A) = E(X)E(1_A) = E(E(X)1_A).
\]

**Rule 4** If \( X \) is \( B \)-measurable, then \( E(X|B) = X \).

**Rule 5** If \( Y \) is a bounded and \( B \)-measurable random variable, then

\[
E(YX|B) = YE(X|B).
\]

In fact, the random variable \( YE(X|B) \) is integrable and \( B \)-measurable, and for all \( A \in B \) we have

\[
E(E(X|B)Y 1_A) = E(XY 1_A),
\]

where the equality follows from (3). This Rule means that \( B \)-measurable random variables behave as constants and can be factorized out of the conditional expectation with respect to \( B \). This property holds if \( X, Y \in L^2(\Omega) \).

**Rule 6** Given two \( \sigma \)-fields \( C \subset B \), then

\[
E(E(X|B)|C) = E(E(X|C)|B) = E(X|C)
\]

**Rule 7** Consider two random variable \( X, Y, Z \), such that \( Z \) is \( B \)-measurable and \( X \) is independent of \( B \). Consider a measurable function \( h(x, z) \) such that the composition \( h(X, Z) \) is an integrable random variable. Then, we have

\[
E(h(X, Z)|B) = E(h(X, z)) |_{z=Z}
\]

That is, we first compute the conditional expectation \( E(h(X, z)) \) for any fixed value \( z \) of the random variable \( Z \) and, afterwards, we replace \( z \) by \( Z \).
Conditional expectation has properties similar to those of ordinary expectation. For instance, the following monotone property holds:

\[ X \leq Y \Rightarrow E(X|B) \leq E(Y|B). \]

This implies \(|E(X|B)| \leq E(|X||B)|\).

Jensen inequality also holds. That is, if \(\varphi\) is a convex function such that \(E(|\varphi(X)|) < \infty\), then

\[ \varphi(E(X|B)) \leq E(\varphi(X)|B). \] (4)

In particular, if we take \(\varphi(x) = |x|^p\) with \(p \geq 1\), we obtain

\[ |E(X|B)|^p \leq E(|X|^p|B), \]

hence, taking expectations, we deduce that if \(E(|X|^p) < \infty\), then \(E(|E(X|B)|^p) < \infty\) and

\[ E(|E(X|B)|^p) \leq E(|X|^p). \] (5)

We can define the conditional probability of an event \(C \in \mathcal{F}\) given a \(\sigma\)-field \(B\) as

\[ P(C|B) = E(1_C|B). \]

Suppose that the \(\sigma\)-field \(B\) is generated by a finite collection of random variables \(Y_1, \ldots, Y_m\). In this case, we will denote the conditional expectation of \(X\) given \(B\) by \(E(X|Y_1, \ldots, Y_m)\). In this case this conditional expectation is the mean of the conditional distribution of \(X\) given \(Y_1, \ldots, Y_m\).

The conditional distribution of \(X\) given \(Y_1, \ldots, Y_m\) is a family of distributions \(p(dx|y_1, \ldots, y_m)\) parameterized by the possible values \(y_1, \ldots, y_m\) of the random variables \(Y_1, \ldots, Y_m\), such that for all \(a < b\)

\[ P(a \leq X \leq b|Y_1, \ldots, Y_m) = \int_a^b p(dx|Y_1, \ldots, Y_m). \]

Then, this implies that

\[ E(X|Y_1, \ldots, Y_m) = \int_{\mathbb{R}} xp(dx|Y_1, \ldots, Y_m). \]

Notice that the conditional expectation \(E(X|Y_1, \ldots, Y_m)\) is a function \(g(Y_1, \ldots, Y_m)\) of the variables \(Y_1, \ldots, Y_m\), where

\[ g(y_1, \ldots, y_m) = \int_{\mathbb{R}} xp(dx|y_1, \ldots, y_m). \]

In particular, if the random variables \(X, Y_1, \ldots, Y_m\) have a joint density \(f(x, y_1, \ldots, y_m)\), then the conditional distribution has the density:

\[ f(x|y_1, \ldots, y_m) = \frac{f(x, y_1, \ldots, y_m)}{\int_{-\infty}^{+\infty} f(x, y_1, \ldots, y_m)dx}, \]
and

\[ E(X|Y_1, \ldots, Y_m) = \int_{-\infty}^{+\infty} xf(x|Y_1, \ldots, Y_m)dx. \]

The set of all square integrable random variables, denoted by \(L^2(\Omega, \mathcal{F}, P)\), is a Hilbert space with the scalar product

\[ \langle Z, Y \rangle = E(ZY). \]

Then, the set of square integrable and \(\mathcal{B}\)-measurable random variables, denoted by \(L^2(\Omega, \mathcal{B}, P)\), is a closed subspace of \(L^2(\Omega, \mathcal{F}, P)\).

Then, given a random variable \(X\) such that \(E(X^2) < \infty\), the conditional expectation \(E(X|\mathcal{B})\) is the projection of \(X\) on the subspace \(L^2(\Omega, \mathcal{B}, P)\). In fact, we have:

(i) \(E(X|\mathcal{B})\) belongs to \(L^2(\Omega, \mathcal{B}, P)\) because it is a \(\mathcal{B}\)-measurable random variable and it is square integrable due to (5).

(ii) \(X - E(X|\mathcal{B})\) is orthogonal to the subspace \(L^2(\Omega, \mathcal{B}, P)\). In fact, for all \(Z \in L^2(\Omega, \mathcal{B}, P)\) we have, using the Rule 5,

\[ E[(X - E(X|\mathcal{B}))Z] = E(XZ) - E(E(X|\mathcal{B})Z) = E(XZ) - E(E(XZ|\mathcal{B})) = 0. \]

As a consequence, \(E(X|\mathcal{B})\) is the random variable in \(L^2(\Omega, \mathcal{B}, P)\) that minimizes the mean square error:

\[ E[(X - E(X|\mathcal{B}))^2] = \min_{Y \in L^2(\Omega, \mathcal{B}, P)} E[(X - Y)^2]. \]

This follows from the relation

\[ E[(X - Y)^2] = E[(X - E(X|\mathcal{B}))^2] + E[(E(X|\mathcal{B}) - Y)^2] \]

and it means that the conditional expectation is the optimal estimator of \(X\) given the \(\sigma\)-field \(\mathcal{B}\).

### 2.2 Discrete Time Martingales

In this section we consider a probability space \((\Omega, \mathcal{F}, P)\) and a nondecreasing sequence of \(\sigma\)-fields

\[ \mathcal{F}_0 \subset \mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots \subset \mathcal{F}_n \subset \cdots \]

contained in \(\mathcal{F}\). A sequence of real random variables \(M = \{M_n, n \geq 0\}\) is called a martingale with respect to the \(\sigma\)-fields \(\{\mathcal{F}_n, n \geq 0\}\) if:

(i) For each \(n \geq 0\), \(M_n\) is \(\mathcal{F}_n\)-measurable (that is, \(M\) is adapted to the filtration \(\{\mathcal{F}_n, n \geq 0\}\)).
(ii) For each $n \geq 0$, $E(|M_n|) < \infty$.

(iii) For each $n \geq 0$,

$$E(M_{n+1}|\mathcal{F}_n) = M_n.$$

The sequence $M = \{M_n, n \geq 0\}$ is called a supermartingale (or submartingale) if property (iii) is replaced by $E(M_{n+1}|\mathcal{F}_n) \leq M_n$ (or $E(M_{n+1}|\mathcal{F}_n) \geq M_n$).

Notice that the martingale property implies that $E(M_n) = E(M_0)$ for all $n$.

On the other hand, condition (iii) can also be written as

$$E(\Delta M_n|\mathcal{F}_{n-1}) = 0,$$

for all $n \geq 1$, where $\Delta M_n = M_n - M_{n-1}$.

**Example 2** Suppose that $\{\xi_n, n \geq 1\}$ are independent centered random variables. Set $M_0 = 0$ and $M_n = \xi_1 + \ldots + \xi_n$, for $n \geq 1$. Then $M_n$ is a martingale with respect to the sequence of $\sigma$-fields $\mathcal{F}_n = \sigma(\xi_1, \ldots, \xi_n)$ for $n \geq 1$, and $\mathcal{F}_0 = \{\emptyset, \Omega\}$. In fact,

$$E(M_{n+1}|\mathcal{F}_n) = E(M_n + \xi_n|\mathcal{F}_n) = M_n + E(\xi_n|\mathcal{F}_n) = M_n + E(\xi_n) = M_n.$$

**Example 3** Suppose that $\{\xi_n, n \geq 1\}$ are independent random variable such that $P(\xi_n = 1) = p$, i.e., $P(\xi_n = -1) = 1-p$, on $0 < p < 1$. Then $M_n = \left(\frac{1-p}{p}\right)^{\xi_1+\ldots+\xi_n}$, $M_0 = 1$, is a martingale with respect to the sequence of $\sigma$-fields $\mathcal{F}_n = \sigma(\xi_1, \ldots, \xi_n)$ for $n \geq 1$, and $\mathcal{F}_0 = \{\emptyset, \Omega\}$. In fact,

$$E(M_{n+1}|\mathcal{F}_n) = E\left(\left(\frac{1-p}{p}\right)^{\xi_1+\ldots+\xi_{n+1}}|\mathcal{F}_n\right)$$

$$= \left(\frac{1-p}{p}\right)^{\xi_1+\ldots+\xi_n} E\left(\left(\frac{1-p}{p}\right)^{\xi_{n+1}}|\mathcal{F}_n\right)$$

$$= M_n E\left(\frac{1-p}{p}\right)^{\xi_{n+1}}$$

$$= M_n.$$

In the two previous examples, $\mathcal{F}_n = \sigma(M_0, \ldots, M_n)$, for all $n \geq 0$. That is, $\{\mathcal{F}_n\}$ is the filtration generated by the process $\{M_n\}$. Usually, when the filtration is not mentioned, we will take $\mathcal{F}_n = \sigma(M_0, \ldots, M_n)$, for all $n \geq 0$. This is always possible due to the following result:

**Lemma 12** Suppose $\{M_n, n \geq 0\}$ is a martingale with respect to a filtration $\{\mathcal{G}_n\}$. Let $\mathcal{F}_n = \sigma(M_0, \ldots, M_n) \subset \mathcal{G}_n$. Then $\{M_n, n \geq 0\}$ is a martingale with respect to a filtration $\{\mathcal{F}_n\}$. 

23
Proof. We have, by the Rule 6 of conditional expectations,

\[ E(M_{n+1} | \mathcal{F}_n) = E(E(M_{n+1} | \mathcal{G}_n) | \mathcal{F}_n) = E(M | \mathcal{F}_n) = M_n. \]

Some elementary properties of martingales:

1. If \{M_n\} is a martingale, then for all \(m \geq n\) we have

\[
E(M_m | \mathcal{F}_n) = M_n.
\]

In fact,

\[
M_n = E(M_{n+1} | \mathcal{F}_n) = E(E(M_{n+2} | \mathcal{F}_{n+1}) | \mathcal{F}_n) = E(M_{n+2} | \mathcal{F}_n) = \ldots = E(M_m | \mathcal{F}_n).
\]

2. \{M_n\} is a submartingale if and only if \{-M_n\} is a supermartingale.

3. If \{M_n\} is a martingale and \(\varphi\) is a convex function such that \(E(|\varphi(M_n)|) < \infty\) for all \(n \geq 0\), then \{\varphi(M_n)\} is a submartingale. In fact, by Jensen’s inequality for the conditional expectation we have

\[
E(\varphi(M_{n+1}) | \mathcal{F}_n) \geq \varphi(E(M_{n+1} | \mathcal{F}_n)) = \varphi(M_n).
\]

In particular, if \{M_n\} is a martingale such that \(E(|M_n|^p) < \infty\) for all \(n \geq 0\) and for some \(p \geq 1\), then \{|M_n|^p\} is a submartingale.

4. If \{M_n\} is a submartingale and \(\varphi\) is a convex and increasing function such that \(E(|\varphi(M_n)|) < \infty\) for all \(n \geq 0\), then \{\varphi(M_n)\} is a submartingale. In fact, by Jensen’s inequality for the conditional expectation we have

\[
E(\varphi(M_{n+1}) | \mathcal{F}_n) \geq \varphi(E(M_{n+1} | \mathcal{F}_n)) \geq \varphi(M_n).
\]

In particular, if \{M_n\} is a submartingale, then \({M_n^+}\) and \({M_n \wedge a}\) are submartingales.

Suppose that \{\mathcal{F}_n, n \geq 0\} is a given filtration. We say that \{H_n, n \geq 1\} is a predictable sequence of random variables if for each \(n \geq 1\), \(H_n\) is \(\mathcal{F}_{n-1}\)-measurable. We define the martingale transform of a martingale \{M_n, n \geq 0\} by a predictable sequence \{H_n, n \geq 1\} as the sequence

\[
(H \cdot M)_n = M_0 + \sum_{j=1}^{n} H_j \Delta M_j.
\]

Proposition 13 If \{M_n, n \geq 0\} is a (sub)martingale and \{H_n, n \geq 1\} is a bounded (nonnegative) predictable sequence, then the martingale transform \{(H \cdot M)_n\} is a (sub)martingale.
Proof. Clearly, for each \( n \geq 0 \) the random variable \((H \cdot M)_n\) is \( \mathcal{F}_n \)-measurable and integrable. On the other hand, if \( n \geq 0 \) we have

\[
E((H \cdot M)_{n+1} - (H \cdot M)_n | \mathcal{F}_n) = E(\Delta M_{n+1} | \mathcal{F}_n) = H_{n+1} E(\Delta M_{n+1} | \mathcal{F}_n) = 0.
\]

We may think of \( H_n \) as the amount of money a gambler will bet at time \( n \).

Suppose that \( \Delta M_n = M_n - M_{n-1} \) is the amount a gambler can win or lose at every step of the game if the bet is 1 Euro, and \( M_0 \) is the initial capital of the gambler. Then, \( M_n \) will be the fortune of the gambler at time \( n \), and \((H \cdot M)_n\) will be the fortune of the gambler if he uses the gambling system \( \{H_n\} \). The fact that \( \{M_n\} \) is a martingale means that the game is fair. So, the previous proposition tells us that if a game is fair, it is also fair regardless the gambling system \( \{H_n\} \).

Suppose that \( M_n = M_0 + \xi_1 + \cdots + \xi_n \), where \( \{\xi_n, n \geq 1\} \) are independent random variable such that \( P(\xi_n = 1) = P(\xi_n = -1) = \frac{1}{2} \). A famous gambling system is defined by \( H_1 = 1 \) and for \( n \geq 2 \), \( H_n = 2H_{n-1} \) if \( \xi_{n-1} = -1 \), and \( H_n = 1 \) if \( \xi_{n-1} = 1 \). In other words, we double our bet when we lose, so that if we lose \( k \) times and then win, our net winnings will be

\[
-1 - 2 - 4 - \cdots - 2^{k-1} + 2^k = 1.
\]

This system seems to provide us with a “sure win”, but this is not true due to the above proposition.

Example 4 Suppose that \( S_n^0, S_n^1, \ldots, S_n^d \) are adapted and positive random variables which represent the prices at time \( n \) of \( d + 1 \) financial assets. We assume that \( S_n^0 = (1 + r)^n \), where \( r > 0 \) is the interest rate, so the asset number 0 is non risky. We denote by \( S_n = (S_n^0, S_n^1, \ldots, S_n^d) \) the vector of prices at time \( n \).

In this context, a portfolio is a family of predictable sequences \( \{\phi_n^i, n \geq 1\} \); \( i = 0, \ldots, d \), such that \( \phi_n^i \) represents the number of assets of type \( i \) at time \( n \). We set \( \phi_n = (\phi_n^0, \phi_n^1, \ldots, \phi_n^d) \). The value of the portfolio at time \( n \geq 1 \) is then

\[
V_n = \phi_n^0 S_n^0 + \phi_n^1 S_n^1 + \cdots + \phi_n^d S_n^d = \phi_n \cdot S_n.
\]

We say that a portfolio is self-financing if for all \( n \geq 1 \)

\[
V_n = V_0 + \sum_{j=1}^n \phi_j \cdot \Delta S_j,
\]

where \( V_0 \) denotes the initial capital of the portfolio. This condition is equivalent to

\[
\phi_n \cdot S_n = \phi_{n+1} \cdot S_n
\]

for all \( n \geq 0 \). Define the discounted prices by

\[
\tilde{S}_n = (1 + r)^{-n} S_n = (1, (1 + r)^{-n} S_n^1, \ldots, (1 + r)^{-n} S_n^d).
\]
Then the discounted value of the portfolio is

\[ \tilde{V}_n = (1 + r)^{-n}V_n = \phi_n \cdot \tilde{S}_n, \]

and the self-financing condition can be written as

\[ \phi_n \cdot \tilde{S}_n = \phi_{n+1} \cdot \tilde{S}_n, \]

for \( n \geq 0 \), that is, \( \tilde{V}_{n+1} - \tilde{V}_n = \phi_{n+1} \cdot (\tilde{S}_{n+1} - \tilde{S}_n) \) and summing in \( n \) we obtain

\[ \tilde{V}_n = V_0 + \sum_{j=1}^{n} \phi_j \cdot \Delta \tilde{S}_j. \]

In particular, if \( d = 1 \), then \( \tilde{V}_n = (\phi^1 \cdot \tilde{S}^1) \) is the martingale transform of the sequence \( \{\tilde{S}^1_n\} \) by the predictable sequence \( \{\phi^1_n\} \). As a consequence, if \( \{\tilde{S}^1_n\} \) is a martingale and \( \{\phi^1_n\} \) is a bounded sequence, \( \{\tilde{V}_n\} \) will also be a martingale.

We say that a probability \( Q \) equivalent to \( P \) (that is, \( P(A) = 0 \iff Q(A) = 0 \)), is a risk-free probability, if in the probability space \((\Omega, \mathcal{F}, Q)\) the sequence of discounted prices \( \tilde{S}_n \) is a martingale with respect to \( \mathcal{F}_n \). Then, the sequence of values of any self-financing portfolio will also be a martingale with respect to \( \mathcal{F}_n \), provided the \( \beta_n \) are bounded.

In the particular case of the binomial model \((d = 1 \text{ and } S_n = S^1_n)\) (also called Ross-Cox-Rubinstein model), we assume that the random variables

\[ T_n = \frac{S_n}{S_{n-1}} = 1 + \frac{\Delta S_n}{S_{n-1}}, \]

\( n = 1, \ldots, N \) are independent and take two different values \( 1+a, 1+b, a < r < b \), with probabilities \( p \), and \( 1-p \), respectively. In this example, the risk-free probability will be

\[ p = \frac{b - r}{b - a}. \]

In fact, for each \( n \geq 1 \),

\[ E(T_n) = (1 + a)p + (1 + b)(1 - p) = 1 + r, \]

and, therefore,

\[ E(\tilde{S}_n \mid \mathcal{F}_{n-1}) = (1 + r)^{-n}E(S_n \mid \mathcal{F}_{n-1}) = (1 + r)^{-n}E(T_nS_{n-1} \mid \mathcal{F}_{n-1}) = (1 + r)^{-n}S_{n-1}E(T_n \mid \mathcal{F}_{n-1}) = (1 + r)^{-1}S_{n-1}E(T_n) = \tilde{S}_{n-1}. \]

Consider a random variable \( H \geq 0 \), \( \mathcal{F}_N \)-measurable, which represents the payoff of a derivative at the maturity time \( N \) on the asset. For instance, for
an European call option with strike price $K$, $H = (S_N - K)^+$. The derivative is replicable if there exists a self-financing portfolio such that $V_N = H$. We will take the value of the portfolio $V_n$ as the price of the derivative at time $n$. In order to compute this price we make use of the martingale property of the sequence $\tilde{V}_n$ and we obtain the following general formula for derivative prices:

$$V_n = (1 + r)^{-(N-n)} E_Q(H|\mathcal{F}_n).$$

In fact,

$$\tilde{V}_n = E_Q(\tilde{V}_N|\mathcal{F}_n) = (1 + r)^{-(N-n)} E_Q(H|\mathcal{F}_n).$$

In particular, for $n = 0$, if the $\sigma$-field $\mathcal{F}_0$ is trivial,

$$V_0 = (1 + r)^{-N} E_Q(H).$$

### 2.3 Stopping Times

Consider an non-decreasing family of $\sigma$-fields

$$\mathcal{F}_0 \subset \mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots$$

in a probability space $(\Omega, \mathcal{F}, P)$. That is $\mathcal{F}_n \subset \mathcal{F}$ for all $n$.

A random variable $T : \Omega \to \{0, 1, 2, \ldots \} \cup \{\infty\}$ is called a stopping time if the event $\{T = n\}$ belongs to $\mathcal{F}_n$ for all $n = 0, 1, 2, \ldots$. Intuitively, $\mathcal{F}_n$ represents the information available at time $n$, and given this information you know when $T$ occurs.

**Example 5** Consider a discrete time stochastic process $\{X_n, n \geq 0\}$ adapted to $\{\mathcal{F}_n, n \geq 0\}$. Let $A$ be a subset of the space state. Then the first hitting time $T_A$ is a stopping time because

$$\{T_A = n\} = \{X_0 \notin A, \ldots, X_{n-1} \notin A, X_n \in A\}.$$

The condition $\{T = n\} \in \mathcal{F}_n$ for all $n \geq 0$ is equivalent to $\{T \leq n\} \in \mathcal{F}_n$ for all $n \geq 0$. This is an immediate consequence of the relations

$$\{T \leq n\} = \cup_{j=1}^{n} \{T = j\},$$

$$\{T = n\} = \{T \leq n\} \cap (\{T \leq n-1\})^c.$$

The extension of the notion of stopping time to continuous time will be inspired by this equivalence. Consider now a continuous parameter non-decreasing family of $\sigma$-fields $\{\mathcal{F}_t, t \geq 0\}$ in a probability space $(\Omega, \mathcal{F}, P)$. A random variable $T : \Omega \to [0, \infty]$ is called a stopping time if the event $\{T \leq t\}$ belongs to $\mathcal{F}_t$ for all $t \geq 0$.

**Example 6** Consider a real-valued stochastic process $\{X_t, t \geq 0\}$ with continuous trajectories, and adapted to $\{\mathcal{F}_t, t \geq 0\}$. The first passage time for a level $a \in \mathbb{R}$ defined by

$$T_a := \inf\{t > 0 : X_t = a\}$$
is a stopping time because

\[ \{ T_a \leq t \} = \left\{ \sup_{0 \leq s \leq t} X_s \geq a \right\} \in \mathcal{F}_t. \]

**Properties of stopping times:**

1. If \( S \) and \( T \) are stopping times, so are \( S \vee T \) and \( S \wedge T \). In fact, this a consequence of the relations

\[
\{ S \vee T \leq t \} = \{ S \leq t \} \cup \{ T \leq t \}, \\
\{ S \wedge T \leq t \} = \{ S \leq t \} \cap \{ T \leq t \}.
\]

2. Given a stopping time \( T \), we can define the \( \sigma \)-field

\[ \mathcal{F}_T = \{ A : A \cap \{ T \leq t \} \in \mathcal{F}_t, \text{ for all } t \geq 0 \}. \]

\( \mathcal{F}_T \) is a \( \sigma \)-field because it contains the empty set, it is stable by complements due to

\[ A^c \cap \{ T \leq t \} = (A \cup \{ T > t \})^c = ((A \cap \{ T \leq t \}) \cup \{ T > t \})^c, \]

and it is stable by countable intersections.

3. If \( S \) and \( T \) are stopping times such that \( S \leq T \), then \( \mathcal{F}_S \subset \mathcal{F}_T \). In fact, if \( A \in \mathcal{F}_S \), then

\[ A \cap \{ T \leq t \} = [A \cap \{ S \leq t \}] \cap \{ T \leq t \} \in \mathcal{F}_t \]

for all \( t \geq 0 \).

4. Let \( \{ X_t \} \) be an adapted stochastic process (with discrete or continuous parameter) and let \( T \) be a stopping time. If the parameter is continuous, we assume that the trajectories of the process \( \{ X_t \} \) are right-continuous. Then the random variable

\[ X_T(\omega) = X_{T(\omega)}(\omega) \]

is \( \mathcal{F}_T \)-measurable. In discrete time this property follows from the relation

\[ \{ X_T \in B \} \cap \{ T = n \} = \{ X_n \in B \} \cap \{ T = n \} \in \mathcal{F}_n \]

for any subset \( B \) of the state space (Borel set if the state space is \( \mathbb{R} \)).
2.4 Optional stopping theorem

Consider a discrete time filtration and suppose that $T$ is a stopping time. Then, the process

$$H_n = 1_{\{T \geq n\}}$$

is predictable. In fact, $\{T \geq n\} = \{T \leq n - 1\} \in \mathcal{F}_{n-1}$. The martingale transform of $\{M_n\}$ by this sequence is

$$(H \cdot M)_n = M_0 + \sum_{j=1}^{\min(T,n)} 1_{\{T \geq j\}} (M_j - M_{j-1})$$

$$= M_0 + \sum_{j=1}^{T \wedge n} (M_j - M_{j-1}) = M_{T \wedge n}.$$

As a consequence, if $\{M_n\}$ is a (sub)martingale, the stopped process $\{M_{T \wedge n}\}$ will be a (sub)martingale.

**Theorem 14 (Optional Stopping Theorem)** Suppose that $\{M_n\}$ is a sub-martingale and $S \leq T \leq m$ are two stopping times bounded by a fixed time $m$. Then

$$E(M_T|\mathcal{F}_S) \geq M_S,$$

with equality in the martingale case.

This theorem implies that $E(M_T) \leq E(M_S)$.

**Proof.** We make the proof only in the martingale case. Notice first that $M_T$ is integrable because

$$|M_T| \leq \sum_{n=0}^{m} |M_n|.$$

Consider the predictable process $H_n = 1_{\{S < n \leq T\} \cap A}$, where $A \in \mathcal{F}_S$. Notice that $\{H_n\}$ is predictable because

$$\{S < n \leq T\} \cap A = \{T < n\}^c \cap [\{S \leq n - 1\} \cap A] \in \mathcal{F}_{n-1}.$$

Moreover, the random variables $H_n$ are nonnegative and bounded by one. Therefore, by Proposition 13, $(H \cdot M)_n$ is a martingale. We have

$$(H \cdot M)_0 = M_0,$$

$$ (H \cdot M)_m = M_0 + 1_A(M_T - M_S).$$

The martingale property of $(H \cdot M)_n$ implies that $E((H \cdot M)_0) = E((H \cdot M)_m)$. Hence,

$$E(1_A(M_T - M_S)) = 0$$

for all $A \in \mathcal{F}_S$ and this implies that $E(M_T|\mathcal{F}_S) = M_S$, because $M_S$ is $\mathcal{F}_S$-measurable. ■
**Theorem 15 (Doob’s Maximal Inequality)** Suppose that \( \{M_n\} \) is a non-negative submartingale and \( \lambda > 0 \). Then

\[
P(\sup_{0 \leq n \leq N} M_n \geq \lambda) \leq \frac{1}{\lambda} E(M_N 1_{\{\sup_{0 \leq n \leq N} M_n \geq \lambda\}}).
\]

**Proof.** Consider the stopping time

\[
T = \inf\{n \geq 0 : M_n \geq \lambda\} \wedge N.
\]

Then, by the Optional Stopping Theorem,

\[
E(M_N) \geq E(M_T) = E(M_T 1_{\{\sup_{0 \leq n \leq N} M_n \geq \lambda\}})
+ E(M_T 1_{\{\sup_{0 \leq n \leq N} M_n < \lambda\}})
\geq \lambda P(\sup_{0 \leq n \leq N} M_n \geq \lambda) + E(M_N 1_{\{\sup_{0 \leq n \leq N} M_n < \lambda\}}).
\]

As a consequence, if \( \{M_n\} \) is a martingale and \( p \geq 1 \), applying Doob’s maximal inequality to the submartingale \( \{|M_n|^p\} \) we obtain

\[
P(\sup_{0 \leq n \leq N} |M_n| \geq \lambda) \leq \frac{1}{\lambda^p} E(|M_N|^p),
\]

which is a generalization of Chebyshev inequality.

### 2.5 Martingale convergence theorems

**Theorem 16 (The Martingale Convergence Theorem)** If \( \{M_n\} \) is a submartingale such that \( \sup_n E(M_n^+) < \infty \), then

\[
[M_n \overset{a.s.}{\to} M]
\]

where \( M \) is an integrable random variable.

As a consequence, any nonnegative martingale converges almost surely. However, the convergence may not be in the mean.

**Example 7** Suppose that \( \{\xi_n, n \geq 1\} \) are independent random variables with distribution \( N(0, \sigma^2) \). Set \( M_0 = 1 \), and

\[
M_n = \exp\left(\sum_{j=1}^{n} \xi_j - \frac{n\sigma^2}{2}\right).
\]

Then, \( \{M_n\} \) is a nonnegative martingale such that \( M_n \overset{a.s.}{\to} 0 \), by the strong law of large numbers, but \( E(M_n) = 1 \) for all \( n \).
Example 8 (Branching processes) Suppose that \( \{ \xi^n, n \geq 1, i \geq 0 \} \) are nonnegative independent identically distributed random variables. Define a sequence \( \{ Z_n \} \) by \( Z_0 = 1 \) and for \( n \geq 1 \)

\[
Z_{n+1} = \begin{cases} 
\xi_n^{n+1} + \cdots + \xi_1^{n+1} & \text{if } Z_n > 0 \\
0 & \text{if } Z_n = 0
\end{cases}
\]

The process \( \{ Z_n \} \) is called a Galton-Watson process. The random variable \( Z_n \) is the number of people in the \( n \)th generation and each member of a generation gives birth independently to an identically distributed number of children. \( p_k = P(\xi^n = k) \) is called the offspring distribution. Set \( \mu = E(\xi^n) \). The process \( Z_n/\mu^n \) is a martingale. In fact,

\[
E(Z_{n+1}|F_n) = \sum_{k=1}^{\infty} E(Z_{n+1}1_{\{Z_n=k\}}|F_n)
= \sum_{k=1}^{\infty} E((\xi_1^{n+1} + \cdots + \xi_k^{n+1}) 1_{\{Z_n=k\}}|F_n)
= \sum_{k=1}^{\infty} 1_{\{Z_n=k\}} E(\xi_1^{n+1} + \cdots + \xi_k^{n+1}|F_n)
= \sum_{k=1}^{\infty} 1_{\{Z_n=k\}} (k\mu) = \mu Z_n.
\]

This implies that \( E(Z_n) = \mu^n \). On the other hand, \( Z_n/\mu^n \) is a nonnegative martingale, so it converges almost surely to a limit. This limit is zero if \( \mu \leq 1 \) and \( \xi^n \) is not identically one. Actually, in this case \( Z_n = 0 \) for all \( n \) sufficiently large. This is intuitive: If each individual on the average gives birth to less than one child, the species dies out. If \( \mu > 1 \) the limit of \( Z_n/\mu^n \) has a change of being nonzero. In this case \( \rho = P(Z_n = 0 \text{ for some } n) < 1 \) is the unique solution of \( \varphi(\rho) = \rho \), where \( \varphi(s) = \sum_{k=0}^{\infty} p_k s^k \) is the generating function of the spring distribution.

The following result established the convergence of the martingale in mean of order \( p \) in the case \( p > 1 \).

**Theorem 17** If \( \{ M_n \} \) is a martingale such that \( \sup_{n} E(|M_n|^p) < \infty \), for some \( p > 1 \), then

\[
[M_n \to M]
\]

almost surely and in mean of order \( p \). Moreover, \( M_n = E(M|F_n) \) for all \( n \).

Example 9 Consider the symmetric random walk \( \{ S_n, n \geq 0 \} \). That is, \( S_0 = 0 \) and for \( n \geq 1 \), \( S_n = \xi_1 + \ldots + \xi_n \) where \( \{ \xi_n, n \geq 1 \} \) are independent random
variables such that \( P(\xi_n = 1) = P(\xi_n = -1) = \frac{1}{2} \). Then \( \{S_n\} \) is a martingale. Set
\[
T = \inf\{n \geq 0 : S_n \notin (a, b)\},
\]
where \( b < 0 < a \). We are going to show that \( E(T) = |ab| \).

In fact, we know that \( \{S_{T \wedge n}\} \) is a martingale. So, \( E(S_{T \wedge n}) = E(S_0) = 0 \). This martingale converges almost surely and in mean of order one because it is uniformly bounded. We know that \( P(T < \infty) = 1 \), because the random walk is recurrent. Hence,
\[
S_{T \wedge n} \overset{a.s.,t}{\longrightarrow} S_T \in \{b,a\}.
\]
Therefore, \( E(S_T) = 0 = aP(S_T = a) + bP(S_T = b) \). From this equation we obtain the absorption probabilities:
\[
P(S_T = a) = \frac{-b}{a-b},
\]
\[
P(S_T = b) = \frac{a}{a-b}.
\]

Now \( \{S_n^2 - n\} \) is also a martingale, and by the same argument, this implies \( E(S_T) = E(T) \), which leads to \( E(T) = -ab \).

### 2.6 Continuous Time Martingales

We assume here that the parameter space \( T \) is \([0, \infty)\), of a finite interval \([a, b]\). A filtration, by definition, is a nondecreasing family of \( \sigma \)-fields \( \{\mathcal{F}_t, t \in T\} \), such that \( \mathcal{F}_t \subset \mathcal{F} \), for all \( t \), satisfying the following properties:

- **i)** Any set \( A \) with probability zero belongs to all the \( \mathcal{F}_t \).
- **ii)** Right-continuity: \( \cap_{t} \mathcal{F}_{t+\frac{1}{n}} = \mathcal{F}_t \), for all \( t \).

We say that a stochastic process \( X = \{X_t, t \in T\} \) is adapted to the filtration \( \{\mathcal{F}_t, t \in T\} \), if for all \( t \), the random variable \( X_t \) is measurable with respect to the \( \sigma \)-field \( \mathcal{F}_t \).

A real continuous time process \( M = \{M_t, t \in T\} \) is called a martingale with respect to the filtration \( \{\mathcal{F}_t, t \in T\} \) if:

- **(i)** \( M \) is \( \mathcal{F}_t \)-adapted.
- **(ii)** For each \( t \geq 0 \), \( E(|M_t|) < \infty \).
- **(iii)** For each \( s \leq t \), \( E(M_t | \mathcal{F}_s) = M_s \).

Property (iii) can also be written as follows:
\[
E(M_t - M_s | \mathcal{F}_s) = 0
\]

Notice that if the time runs in a finite interval \([0, T]\), then we have
\[
M_t = E(M_T | \mathcal{F}_t),
\]
and this implies that the terminal random variable $M_T$ determines the martingale.

In a similar way we can introduce the notions of continuous time submartingale and supermartingale.

As in the discrete time the expectation of a martingale is constant:

$$E(M_t) = E(M_0).$$

Also, most of the properties of discrete time martingales hold in continuous time. For instance, we have the following version of Doob’s maximal inequality:

**Proposition 18** Let \( \{ \xi_t, 0 \leq t \leq T \} \) be a nonnegative continuous submartingale. Then, for all \( p \geq 1 \) and all \( \lambda > 0 \) we have

$$P \left( \sup_{0 \leq t \leq T} \xi_t \geq \lambda \right) \leq \frac{1}{\lambda^p} E(\xi_T^p 1_{\{\sup_{0 \leq t \leq T} \xi_t \geq \lambda\}}).$$

Moreover, if \( p > 1 \), then

$$E \left( \sup_{0 \leq t \leq T} \xi_t^p \right) \leq \left( \frac{p}{p - 1} \right)^p E(\xi_T^p).$$

Notice that if \( M \) is a martingale, then its absolute value is a nonnegative submartingale, and the previous inequality allows us to estimate moments of \( \sup_{0 \leq t \leq T} |M_t| \).

**Exercises**

2.1 Let \( X \) and \( Y \) be two independent random variables such that \( P(X = 1) = P(Y = 1) = p \), and \( P(X = 0) = P(Y = 0) = 1 - p \). Set \( Z = 1_{\{X+Y=0\}} \). Compute \( E(X|Z) \) and \( E(Y|Z) \). Are these random variables still independent?

2.2 Let \( \{Y_n\}_{n \geq 1} \) be a sequence of independent random variable uniformly distributed in \([-1, 1]\). Set \( S_0 = 0 \) and \( S_n = Y_1 + \cdots + Y_n \) if \( n \geq 1 \). Check whether the following sequences are martingales:

\[
M_n^{(1)} = \sum_{k=1}^{n} S_{k-1}^2 Y_k, \quad n \geq 1, \quad M_0^{(1)} = 0
\]

\[
M_n^{(2)} = S_n^2 - \frac{n}{3}, \quad M_0^{(2)} = 0.
\]

2.3 Consider a sequence of independent random variables \( \{X_n\}_{n \geq 1} \) with laws \( N(0, \sigma^2) \). Define

$$Y_n = \exp \left( a \sum_{k=1}^{n} X_k - n\sigma^2 \right),$$

where \( a \) is a real parameter and \( Y_0 = 1 \). For which values of \( a \) the sequence \( Y_n \) is a martingale?
2.4 Let \( Y_1, Y_2, \ldots \) be nonnegative independent and identically distributed random variables with \( E(Y_n) = 1 \). Show that \( X_0 = 1, X_n = Y_1 Y_2 \cdots Y_n \) defines a martingale. Show that the almost sure limit of \( X_n \) is zero if \( P(Y_n = 1) < 1 \) (Apply the strong law of large numbers to log \( Y_n \)).

2.5 Let \( S_n \) be the total assets of an insurance company at the end of the year \( n \). In year \( n \), premiums totaling \( c > 0 \) are received and claims \( \xi_n \) are paid where \( \xi_n \) has the normal distribution \( N(\mu, \sigma^2) \) and \( \mu < c \). The company is ruined if assets drop to 0 or less. Show that

\[
P(\text{ruin}) \leq \exp\left(-2\left(c - \mu\right)S_0 / \sigma^2\right).
\]

2.6 Let \( S_n \) be an asymmetric random walk with \( p > 1/2 \), and let \( T = \inf\{n : S_n = 1\} \). Show that \( S_n - (p - q)n \) is a martingale. Use this property to check that \( E(T) = 1/(2p - 1) \). Using the fact that \( (S_n - (p - q)n)^2 - \sigma^2n \) is a martingale, where \( \sigma^2 = 1 - (p - q)^2 \), show that \( \text{Var}(T) = (1 - (p - q)^2) / (p - q)^3 \).

3 Stochastic Calculus

3.1 Brownian motion

In 1827 Robert Brown observed the complex and erratic motion of grains of pollen suspended in a liquid. It was later discovered that such irregular motion comes from the extremely large number of collisions of the suspended pollen grains with the molecules of the liquid. In the 20's Norbert Wiener presented a mathematical model for this motion based on the theory of stochastic processes. The position of a particle at each time \( t \geq 0 \) is a three dimensional random vector \( B_t \).

The mathematical definition of a Brownian motion is the following:

**Definition 19** A stochastic process \( \{B_t, t \geq 0\} \) is called a Brownian motion if it satisfies the following conditions:

i) \( B_0 = 0 \)

ii) For all \( 0 \leq t_1 < \cdots < t_n \) the increments \( B_{t_n} - B_{t_{n-1}}, \ldots, B_{t_2} - B_{t_1} \), are independent random variables.

iii) If \( 0 \leq s < t \), the increment \( B_t - B_s \) has the normal distribution \( N(0, t - s) \)

iv) The process \( \{B_t\} \) has continuous trajectories.

Remarks:

1) Brownian motion is a Gaussian process. In fact, the probability distribution of a random vector \( (B_{t_1}, \ldots, B_{t_n}) \), for \( 0 < t_1 < \cdots < t_n \), is normal, because this vector is a linear transformation of the vector \( (B_{t_1}, B_{t_2} - B_{t_1}, \ldots, B_{t_n} - B_{t_{n-1}}) \) which has a joint normal distribution, because its components are independent and normal.
2) The mean and autocovariance functions of the Brownian motion are:

\[ E(B_t) = 0 \]
\[ E(B_s B_t) = E(B_s (B_t - B_s + B_s)) = E(B_s (B_t - B_s)) + E(B_s^2) = s = \min(s, t) \]

if \( s \leq t \). It is easy to show that a Gaussian process with zero mean and autocovariance function \( \Gamma_X(s, t) = \min(s, t) \), satisfies the above conditions i), ii) and iii).

3) The autocovariance function \( \Gamma_X(s, t) = \min(s, t) \) is nonnegative definite because it can be written as

\[ \min(s, t) = \int_0^\infty 1_{[0, s]}(r)1_{[0, t]}(r)dr, \]

so

\[ \sum_{i,j=1}^n a_i a_j \min(t_i, t_j) = \sum_{i,j=1}^n a_i a_j \int_0^\infty 1_{[0, t_i]}(r)1_{[0, t_j]}(r)dr \]
\[ = \int_0^\infty \left[ \sum_{i=1}^n a_i 1_{[0, t_i]}(r) \right]^2 dr \geq 0. \]

Therefore, by Kolmogorov’s theorem there exists a Gaussian process with zero mean and covariance function \( \Gamma_X(s, t) = \min(s, t) \). On the other hand, Kolmogorov’s continuity criterion allows to choose a version of this process with continuous trajectories. Indeed, the increment \( B_t - B_s \) has the normal distribution \( N(0, t - s) \), and this implies that for any natural number \( k \) we have

\[ E \left[ (B_t - B_s)^{2k} \right] = \frac{(2k)!}{2^k k!} (t - s)^k. \]

As a consequence, the Brownian motion has a Hölder continuous version of order \( \gamma < \frac{k-1}{2k} \), for any \( k \geq 2 \). This implies that we can choose any \( \gamma < \frac{1}{2} \). That means that for all \( \varepsilon > 0 \) there exists a random variable \( G_{\varepsilon,T} \) such that

\[ |B_t - B_s| \leq G_{\varepsilon,T}|t - s|^{\frac{1}{2} - \varepsilon}, \]

for all \( s, t \in [0, T] \).

4) In the definition of the Brownian motion we have assumed that the probability space \((\Omega, \mathcal{F}, P)\) is arbitrary. The mapping

\[ \Omega \to C([0, \infty), \mathbb{R}) \]
\[ \omega \to B(\omega) \]

induces a probability measure \( P_B = P \circ B^{-1} \), called the Wiener measure, on the space of continuous functions \( C = C([0, \infty), \mathbb{R}) \) equipped with its Borel \( \sigma \)-field \( B_C \). Then we can take as canonical probability space for the Brownian motion the space \( (C, B_C, P_B) \). In this canonical space, the random variables are the evaluation maps: \( X_t(\omega) = \omega(t) \).
3.1.1 Brownian motion on $\mathbb{R}^d$

We say that a stochastic process $B = \{B_t, t \geq 0\}$ is a Brownian motion on $\mathbb{R}^d$, if the components $\{B^i_t, t \geq 0\}$ are one-dimensional independent Brownian motions. The process $B$ is a Gaussian process, with mean zero and covariance function

$$E(B^i_t B^j_s) = \delta_{ij} \min(s,t).$$

3.1.2 Quadratic variation

Let $X = \{X_t, t \geq 0\}$ be a real-valued continuous stochastic process adapted to a filtration $\{\mathcal{F}_t, t \geq 0\}$. Fix a finite interval $[0, T]$, and denote by $\pi$ a partition of this interval $\pi = \{0 = t_0 < t_1 < \cdots < t_m = T\}$.

Define $|\pi| = \max_{1 \leq k \leq m} \Delta t_k$, where $\Delta t_k = t_k - t_{k-1}$, and $X^\pi_t = \sum_{k=1}^m (X_{t_k \wedge t} - X_{t_{k-1} \wedge t})^2$.

**Definition 20** If for any sequence of partitions $\{\pi^n, n \geq 1\}$ such that $|\pi^n| \to 0$, as $n$ tends to infinity, we have

$$X^\pi_t \to \langle X \rangle_t$$

in probability for all $t \in [0, T]$, we say that the process $\langle X \rangle_t$ is the quadratic variation of the process $X$.

In a similar way, the quadratic covariation of two continuous adapted processes $X$ and $Y$ is defined as

$$\langle X, Y \rangle_t = \lim_{n \to \infty} \sum_{k=1}^m (X_{t_k \wedge t} - X_{t_{k-1} \wedge t})(Y_{t_k \wedge t} - Y_{t_{k-1} \wedge t}).$$

The following relation holds

$$\langle X, Y \rangle_t = \frac{1}{4} (\langle X + Y \rangle_t - \langle X - Y \rangle_t),$$

provided that one of the sides of this equality exists.

**Example 1.** Suppose that the process $X$ has trajectories with bounded variation on the time interval $[0, T]$, that is,

$$V_T(X) = \sup_{\pi} \sum_{k=1}^m |X_{t_k} - X_{t_{k-1}}| < \infty.$$ 

This is true, for instance, if $X_t = \int_0^t b_s ds$, because in this case $V_T(X) \leq \int_0^T |b_s| ds < \infty$. Then, $\langle X \rangle_t = 0$ because

$$X^\pi_t \leq V_T(X) \sup_{1 \leq k \leq m} \left| X_{t_k \wedge t} - X_{t_{k-1} \wedge t} \right| \to 0$$

36
almost surely, due to the continuity of the trajectories of the process $X$.

**Example 2.** Consider a Brownian motion $B$. Then, $\langle B \rangle_t = t$. Set $Y_k = B_{tk/h} - B_{tk-1/h}$. We will show that $\sum_{k=1}^m Y_k^2$ converges in $L^2(\Omega)$ to $t$ as $|\pi|$ tends to zero:

$$E \left[ \left( \sum_{k=1}^m Y_k^2 - t \right)^2 \right] = E \left[ \left. \sum_{k=1}^m [Y_k^2 - \Delta t_k] \right)^2 \right]$$

$$= \sum_{k=1}^m E \left[ \left. [Y_k^2 - \Delta t_k]^2 \right) \right]$$

$$= \sum_{k=1}^m \left[ 3(\Delta t_k)^2 - 2(\Delta t_k)^2 + (\Delta t_k)^2 \right]$$

$$\leq 2 \sum_{k=1}^m (\Delta t_k)^2$$

Taking into account both examples, we deduce that the total variation of the Brownian motion on an interval must be infinite almost surely.

**Example 3.** Consider a Brownian motion $B$ on $\mathbb{R}^d$. Then, $\langle B^i, B^j \rangle_t = 0$ if $i \neq j$. Indeed, set $Y_k = (B_{tk/h}^i - B_{tk-1/h}^i)(B_{tk/h}^j - B_{tk-1/h}^j)$. We will show that $\sum_{k=1}^m Y_k$ converges in $L^2(\Omega)$ to 0 as $|\pi|$ tends to zero:

$$E \left[ \left( \sum_{k=1}^m Y_k \right)^2 \right] = \sum_{k=1}^m E \left( Y_k^2 \right)$$

$$= \sum_{k=1}^m (\Delta t_k)^2$$

$$\leq 2m (\Delta t_k)^2$$

3.1.3 Self-similarity

Suppose that $B$ is a one-dimensional Brownian motion. For any $a > 0$ the process

$$\{a^{-1/2}B_{at}, t \geq 0\}$$

is a Brownian motion. In fact, this process verifies easily properties (i) to (iv).

3.1.4 Stochastic Processes Related to Brownian Motion

1. **Brownian bridge**: Consider the process

$$X_t = B_t - tB_1,$$

$t \in [0,1]$. It is a centered normal process with autocovariance function

$$E(X_t X_s) = \min(s,t) - st,$$

which verifies $X_0 = 0, X_1 = 0$. 37
2. Brownian motion with drift: Consider the process
\[ X_t = \sigma B_t + \mu t, \]
t \geq 0, where \( \sigma > 0 \) and \( \mu \in \mathbb{R} \) are constants. It is a Gaussian process with
\[ E(X_t) = \mu t, \]
\[ \Gamma_X(s,t) = \sigma^2 \min(s,t). \]

3. Geometric Brownian motion: It is the stochastic process proposed by Black, Scholes and Merton as model for the curve of prices of financial assets. By definition this process is given by
\[ X_t = e^{\sigma B_t + \mu t}, \]
t \geq 0, where \( \sigma > 0 \) and \( \mu \in \mathbb{R} \) are constants. That is, this process is the exponential of a Brownian motion with drift. This process is not Gaussian, and the probability distribution of \( X_t \) is lognormal.

3.1.5 Simulation of the Brownian Motion

Brownian motion can be regarded as the limit of a symmetric random walk. Indeed, fix a time interval \([0,T]\). Consider \( n \) independent and identically distributed random variables \( \xi_1, \ldots, \xi_n \) with zero mean and variance \( \frac{T}{n} \). Define the partial sums
\[ R_k = \xi_1 + \cdots + \xi_k, \ k = 1, \ldots, n. \]
By the Central Limit Theorem the sequence \( R_n \) converges, as \( n \) tends to infinity, to the normal distribution \( N(0,T) \).

Consider the continuous stochastic process \( S_n(t) \) defined by linear interpolation from the values
\[ S_n\left( \frac{kT}{n} \right) = R_k \ k = 0, \ldots, n. \]
Then, a functional version of the Central Limit Theorem, known as Donsker Invariance Principle, says that the sequence of stochastic processes \( S_n(t) \) converges in law to the Brownian motion on \([0,T]\). This means that for any continuous and bounded function \( \varphi : C([0,T]) \to \mathbb{R} \), we have
\[ E(\varphi(S_n)) \to E(\varphi(B)), \]
as \( n \) tends to infinity.

The trajectories of the Brownian motion can also be simulated by means of Fourier series with random coefficients. Suppose that \( \{e_n, n \geq 0\} \) is an orthonormal basis of the Hilbert space \( L^2([0,T]) \). Suppose that \( \{Z_n, n \geq 0\} \) are independent random variables with law \( N(0,1) \). Then, the random series
\[ \sum_{n=0}^{\infty} Z_n \int_0^t e_n(s)ds \]
converges uniformly on $[0, T]$, for almost all $\omega$, to a Brownian motion $\{B_t, t \in [0, T]\}$, that is,

$$\sup_{0 \leq t \leq T} \left| \sum_{n=0}^{N} Z_n \int_{0}^{t} e_n(s)ds - B_t \right| \xrightarrow{a.s.} 0.$$ 

This convergence also holds in mean square. Notice that

$$E \left[ \left( \sum_{n=0}^{N} Z_n \int_{0}^{t} e_n(r)dr \right) \left( \sum_{n=0}^{N} Z_n \int_{0}^{s} e_n(r)dr \right) \right] \xrightarrow{N \to \infty} \langle 1_{[0,t]}, 1_{[0,s]} \rangle \mathbb{L}^2([0,T]).$$

In particular, if we take the basis formed by trigonometric functions, $e_n(t) = \frac{1}{\sqrt{\pi}} \cos(nt/2)$, for $n \geq 1$, and $e_0(t) = \frac{1}{\sqrt{2\pi}}$, on the interval $[0,2\pi]$, we obtain the Paley-Wiener representation of Brownian motion:

$$B_t = Z_0 \frac{t}{\sqrt{2\pi}} + \frac{2}{\sqrt{\pi}} \sum_{n=1}^{\infty} Z_n \frac{\sin(nt/2)}{n}, \quad t \in [0,2\pi].$$

In order to use this formula to get a simulation of Brownian motion, we have to choose some number $M$ of trigonometric functions and a number $N$ of discretization points:

$$Z_0 \frac{t_j}{\sqrt{2\pi}} + \frac{2}{\sqrt{\pi}} \sum_{n=1}^{M} Z_n \frac{\sin(nt_j/2)}{n}, \quad \text{where} \quad t_j = \frac{2\pi j}{N}, \quad j = 0, 1, \ldots, N.$$  

3.2 Martingales Related with Brownian Motion

Consider a Brownian motion $\{B_t, t \geq 0\}$ defined on a probability space $(\Omega, \mathcal{F}, P)$. For any time $t$, we define the $\sigma$-field $\mathcal{F}_t$ generated by the random variables $\{B_s, s \leq t\}$ and the events in $\mathcal{F}$ of probability zero. That is, $\mathcal{F}_t$ is the smallest $\sigma$-field that contains the sets of the form

$$\{B_s \in A\} \cup N$$

where $0 \leq s \leq t$, $A$ is a Borel subset of $\mathbb{R}$, and $N \in \mathcal{F}$ is such that $P(N) = 0$. Notice that $\mathcal{F}_s \subset \mathcal{F}_t$ if $s \leq t$, that is, $\{\mathcal{F}_t, t \geq 0\}$ is a non-decreasing family of $\sigma$-fields. It turns out that this family of $\sigma$-fields is right-continuous, and then $\{\mathcal{F}_t, t \geq 0\}$ is a filtration in the probability space $(\Omega, \mathcal{F}, P)$.  

39
If $B_t$ is a Brownian motion and $\mathcal{F}_t$ is the filtration generated by $B_t$, then, the processes
\[
\begin{align*}
B_t \\
B_t^2 - t \\
\exp(aB_t - \frac{a^2 t}{2})
\end{align*}
\]
are martingales. In fact, $B_t$ is a martingale because
\[
E(B_t - B_s | \mathcal{F}_s) = E(B_t - B_s) = 0.
\]
For $B_t^2 - t$, we can write, using the properties of the conditional expectation, for $s < t$
\[
\begin{align*}
E(B_t^2 | \mathcal{F}_s) &= E((B_t - B_s + B_s)^2 | \mathcal{F}_s) \\
&= E((B_t - B_s)^2 | \mathcal{F}_s) + 2E((B_t - B_s) B_s | \mathcal{F}_s) \\
&= E(B_t - B_s)^2 + 2B_sE((B_t - B_s) | \mathcal{F}_s) + B_s^2 \\
&= t - s + B_s^2.
\end{align*}
\]
Finally, for $\exp(aB_t - \frac{a^2 t}{2})$ we have
\[
E(e^{aB_t - \frac{a^2 t}{2}} | \mathcal{F}_s) = e^{aB_t} E(e^{a(B_t - B_s) - \frac{a^2 t}{2}} | \mathcal{F}_s) \\
= e^{aB_t} E(e^{a(B_t - B_s) - \frac{a^2 t}{2}}) \\
= e^{aB_t} e^{\frac{a^2 (t-s)}{2} - \frac{a^2 t}{2}} = e^{aB_t} - \frac{a^2 t}{2}.
\]
As an application of the martingale property of this process we will compute the probability distribution of the arrival time of the Brownian motion to some fixed level.

**Example 1** Let $B_t$ be a Brownian motion and $\mathcal{F}_t$ the filtration generated by $B_t$. Consider the stopping time
\[
\tau_a = \inf\{t \geq 0 : B_t = a\},
\]
where $a > 0$. The process $M_t = e^{\lambda B_t - \frac{\lambda^2 t}{2}}$ is a martingale such that
\[
E(M_t) = E(M_0) = 1.
\]
By the Optional Stopping Theorem we obtain
\[
E(M_{\tau_a \wedge N}) = 1,
\]
for all $N \geq 1$. Notice that
\[
M_{\tau_a \wedge N} = \exp \left( \lambda B_{\tau_a \wedge N} - \frac{\lambda^2 (\tau_a \wedge N)}{2} \right) \leq e^{a\lambda}.
\]
On the other hand,

\[
\lim_{N \to \infty} M_{\tau_a \wedge N} = M_{\tau_a} \quad \text{if} \quad \tau_a < \infty
\]
\[
\lim_{N \to \infty} M_{\tau_a \wedge N} = 0 \quad \text{if} \quad \tau_a = \infty
\]

and the dominated convergence theorem implies

\[
E \left( 1_{\{\tau_a < \infty\}} M_{\tau_a} \right) = 1,
\]

that is,

\[
E \left( 1_{\{\tau_a < \infty\}} \exp \left( -\frac{\lambda^2 \tau_a}{2} \right) \right) = e^{-\lambda a}.
\]

Letting \( \lambda \downarrow 0 \) we obtain

\[
P(\tau_a < \infty) = 1,
\]

and, consequently,

\[
E \left( \exp \left( -\frac{\lambda^2 \tau_a}{2} \right) \right) = e^{-\lambda a}.
\]

With the change of variables \( \frac{\lambda^2}{2} = \alpha \), we get

\[
E \left( \exp (-\alpha \tau_a) \right) = e^{-\sqrt{2} \alpha a}. \quad (8)
\]

From this expression we can compute the distribution function of the random variable \( \tau_a \):

\[
P(\tau_a \leq t) = \int_0^t \frac{ae^{-a^2/2s}}{\sqrt{2\pi s^3}} ds.
\]

On the other hand, the expectation of \( \tau_a \) can be obtained by computing the derivative of (8) with respect to the variable \( a \):

\[
E \left( \tau_a \exp (-\alpha \tau_a) \right) = \frac{ae^{-\sqrt{2} \alpha a}}{\sqrt{2} \alpha},
\]

and letting \( \alpha \downarrow 0 \) we obtain \( E(\tau_a) = +\infty \).

### 3.3 Stochastic Integrals

We want to define stochastic integrals of the form.

\[
\int_0^T u_t dB_t.
\]

One possibility is to interpret this integral as a path-wise Riemann Stieltjes integral. That means, if we consider a sequence of partitions of an interval \([0, T] \):

\[
\tau_n : 0 = t_0^n < t_1^n < \cdots < t_{k_n-1}^n < t_{k_n}^n = T
\]

and intermediate points:

\[
\sigma_n : t_i^n \leq s_i^n \leq t_{i+1}^n, \quad i = 0, \ldots, k_n - 1,
\]
such that \( \sup_i (t^n_i - t^n_{i-1}) \xrightarrow{n \to \infty} 0 \), then, given two functions \( f \) and \( g \) on the interval \([0, T]\), the Riemann Stieltjes integral \( \int_0^T f \, dg \) is defined as
\[
\lim_{n \to \infty} \sum_{i=1}^n f(s_{i-1}) \Delta g_i
\]
provided this limit exists and it is independent of the sequences \( \tau_n \) and \( \sigma_n \), where \( \Delta g_i = g(t_i) - g(t_{i-1}) \). The Riemann Stieltjes integral \( \int_0^T f \, dg \) exists if \( f \) is continuous and \( g \) has bounded variation, that is,
\[
\sup_{\tau} \sum_i |\Delta g_i| < \infty.
\]
In particular, if \( g \) is continuously differentiable, \( \int_0^T f \, dg = \int_0^T f(t)g'(t) \, dt \).

We know that the trajectories of Brownian motion have infinite variation on any finite interval. So, we cannot use this result to define the path-wise Riemann-Stieltjes integral \( \int_0^T u_t(\omega) \, dB_t(\omega) \) for a continuous process \( u \). Note, however, that if \( u \) has continuously differentiable trajectories, then the path-wise Riemann Stieltjes integral \( \int_0^T u_t(\omega) \, dB_t(\omega) \) exists and it can be computed integrating by parts:
\[
\int_0^T u_t \, dB_t = u_T B_T - \int_0^T u'_t B_t \, dt.
\]

We are going to construct the integral \( \int_0^T u_t \, dB_t \) by means of a global probabilistic approach.

Suppose that \( \{\mathcal{F}_t, t \geq 0\} \) is a filtration and \( B = \{B_t, t \in [0, T]\} \) is an \( \mathcal{F}_t \)-Brownian motion, that is a Brownian motion, adapted to the filtration \( \{\mathcal{F}_t, t \geq 0\} \), and such that for all \( s < t \), the increment \( B_t - B_s \) is independent of \( \mathcal{F}_s \). For instance, \( \{\mathcal{F}_t, t \geq 0\} \) can be the filtration generated by the Brownian motion.

We denote by \( \mathcal{P} \) the predictable \( \sigma \)-field on product space \([0, T] \times \Omega\), defined as the \( \sigma \)-field generated by the sets of the form \((s, t] \times A\), where \( A \in \mathcal{F}_s \). We say that a stochastic process \( u = \{u_t, t \in [0, T]\} \) is measurable if the mapping \((s, \omega) \mapsto u_s(\omega)\) is measurable on the product space \([0, T] \times \Omega\) with respect to the product \( \sigma \)-field \( \mathcal{B}_{[0,T]} \times \mathcal{F} \). We say that \( u \) is predictable if the mapping \((s, \omega) \mapsto u_s(\omega)\) is measurable with respect to the predictable \( \sigma \)-field \( \mathcal{P} \). Any predictable process is measurable and adapted.

Denote by
\[
L^2_{\alpha,T} = L^2([0, T] \times \Omega, \mathcal{P}, dt \times P) \subset L^2([0, T] \times \Omega, \mathcal{B}_{[0,T]} \otimes \mathcal{F}, dt \times P),
\]
the space of predictable stochastic processes \( u = \{u_t, t \in [0, T]\} \) such that \( E \left( \int_0^T u_t^2 \, dt \right) < \infty \). Note that by Fubini’s theorem
\[
E \left( \int_0^T u_t^2 \, dt \right) = \int_0^T E \left( u_t^2 \right) \, dt.
\]
Also, $L^2_{a,T}$ is a closed subspace of the Hilbert space $L^2([0,T] \times \Omega)$.

We will define the stochastic integral $\int_0^T u_t dB_t$ for processes $u$ in $L^2_{a,T}$ as the limit in mean square of the integral of simple processes. By definition a process $u$ in $L^2_{a,T}$ is a simple process if it is of the form

$$u_t = \sum_{j=1}^{n} \phi_j 1_{(t_{j-1}, t_j)}(t),$$

where $0 = t_0 < t_1 < \cdots < t_n = T$ and $\phi_j$ are square integrable $\mathcal{F}_{t_{j-1}}$-measurable random variables. Given a simple process $u$ of the form (9) we define the stochastic integral of $u$ with respect to the Brownian motion $B$ as

$$\int_0^T u_t dB_t = \sum_{j=1}^{n} \phi_j (B_{t_j} - B_{t_{j-1}}).$$

The stochastic integral defined on the space $\mathcal{E}$ of simple processes possesses has zero mean and satisfies the following isometry property:

$$E \left[ \left( \int_0^T u_t dB_t \right)^2 \right] = E \left( \int_0^T u_t^2 dt \right).$$

**Proof of the isometry property:** Set $\Delta B_j = B_{t_j} - B_{t_{j-1}}$. Then

$$E (\phi_i \phi_j \Delta B_i \Delta B_j) = \begin{cases} 0 & \text{if } i \neq j \\ E (\phi_j^2) (t_j - t_{j-1}) & \text{if } i = j \end{cases}$$

because if $i < j$ the random variables $\phi_i \phi_j \Delta B_i$ and $\Delta B_j$ are independent and if $i = j$ the random variables $\phi_i^2$ and $(\Delta B_i)^2$ are independent. So, we obtain

$$E \left( \int_0^T u_t dB_t \right)^2 = \sum_{i,j=1}^{n} E (\phi_i \phi_j \Delta B_i \Delta B_j) = \sum_{i=1}^{n} E (\phi_i^2) (t_i - t_{i-1})$$

$$= E \left( \int_0^T u_t^2 dt \right).$$

□

The extension of the stochastic integral to processes in the class $L^2_{a,T}$ is based on the following approximation result:

**Lemma 21** If $u$ is a process in $L^2_{a,T}$ then, there exists a sequence of simple processes $u^{(n)}$ such that

$$\lim_{n \to \infty} E \left( \int_0^T |u_t - u_t^{(n)}|^2 dt \right) = 0.$$ 

**Proof:** The proof of this Lemma will be done in two steps:
1. Suppose first that the process $u$ is continuous in mean square. In this case, we can choose the approximating sequence

$$u_t^{(n)} = \sum_{j=1}^{n} u_{t_{j-1}} \mathbf{1}_{(t_{j-1}, t_j]}(t),$$

where $t_j = \frac{t^2}{n}$. The continuity in mean square of $u$ implies that

$$E \left( \int_0^T |u_t - u_t^{(n)}|^2 \, dt \right) \leq T \sup_{|t-s| \leq T/n} E \left( |u_t - u_s|^2 \right),$$

which converges to zero as $n$ tends to infinity.

2. Suppose now that $u$ is an arbitrary process in the class $L^2_{a,T}$. Then, we need to show that there exists a sequence $v^{(n)}$, of processes in $L^2_{a,T}$, continuous in mean square and such that

$$\lim_{n \to \infty} E \left( \int_0^T |u_t - v_t^{(n)}|^2 \, dt \right) = 0.$$  \hfill (13)

In order to find this sequence we set

$$v_t^{(n)} = n \int_{t-\frac{1}{n}}^{t} u_s ds = n \left( \int_0^t u_s ds - \int_0^{t-\frac{1}{n}} u_s ds \right),$$

with the convention $u(s) = 0$ if $s < 0$. These processes are continuous in mean square (actually, they have continuous trajectories) and they belong to the class $L^2_{a,T}$. Furthermore, (13) holds because for each $(t, \omega)$ we have

$$\int_0^T \left| u(t, \omega) - v^{(n)}(t, \omega) \right|^2 \, dt \xrightarrow{n \to \infty} 0$$

(this is a consequence of the fact that $v_t^{(n)}$ is defined from $u_t$ by means of a convolution with the kernel $n1_{[-\frac{1}{n}, 0]}$) and we can apply the dominated convergence theorem on the product space $[0, T] \times \Omega$ because

$$\int_0^T \left| v^{(n)}(t, \omega) \right|^2 \, dt \leq \int_0^T |u(t, \omega)|^2 \, dt.$$  

□

**Definition 22** The stochastic integral of a process $u$ in the $L^2_{a,T}$ is defined as the following limit in mean square

$$\int_0^T u_t dB_t = \lim_{n \to \infty} \int_0^T u_t^{(n)} dB_t,$$  \hfill (14)

where $u^{(n)}$ is an approximating sequence of simple processes that satisfy (12).
Notice that the limit (14) exists because the sequence of random variables \( \int_0^T u^{(n)}_t dB_t \) is Cauchy in the space \( L^2(\Omega) \), due to the isometry property (11):

\[
E \left[ \left( \int_0^T u^{(n)}_t dB_t - \int_0^T u^{(m)}_t dB_t \right)^2 \right] = E \left( \int_0^T (u^{(n)}_t - u^{(m)}_t)^2 dt \right)
\leq 2E \left( \int_0^T (u^{(n)}_t - u^{(m)}_t)^2 dt \right)
+ 2E \left( \int_0^T (u^{(n)}_t - u^{(m)}_t)^2 dt \right) \to 0.
\]

On the other hand, the limit (14) does not depend on the approximating sequence \( u^{(n)}_t \).

Properties of the stochastic integral:

1.- Isometry:

\[
E \left[ \left( \int_0^T u_t dB_t \right)^2 \right] = E \left( \int_0^T u_t^2 dt \right).
\]

2.- Mean zero:

\[
E \left[ \left( \int_0^T u_t dB_t \right) \right] = 0.
\]

3.- Linearity:

\[
\int_0^T (au_t + bv_t) dB_t = a \int_0^T u_t dB_t + b \int_0^T v_t dB_t.
\]

4.- Local property: \( \int_0^T u_t dB_t = 0 \) almost surely, on the set \( G = \{ \int_0^T u_t^2 dt = 0 \} \).

Local property holds because on the set \( G \) the approximating sequence

\[
u^{(n,m,N)}_t = \sum_{j=1}^n m \left[ \int_{\frac{(j-1)T}{n}}^{\frac{jT}{n}} u_s ds \right] \mathbf{1}_{\left( \frac{(j-1)T}{n}, \frac{jT}{n} \right]}(t)
\]

vanishes.

**Example 1**

\[
\int_0^T B_t dB_t = \frac{1}{2} B_T^2 - \frac{1}{2} T.
\]

The process \( B_t \) being continuous in mean square, we can choose as approximating sequence

\[
u^{(n)}_t = \sum_{j=1}^n B_{t_{j-1}} \mathbf{1}_{(t_{j-1},t_j]}(t),
\]
where \( t_j = \frac{jT}{n} \), and we obtain
\[
\int_0^T B_t \, dB_t = \lim_{n \to \infty} \sum_{j=1}^n B_{t_j-1} (B_{t_j} - B_{t_{j-1}})
\]
\[
= \frac{1}{2} \lim_{n \to \infty} (B_{t_j}^2 - B_{t_{j-1}}^2) - \frac{1}{2} \lim_{n \to \infty} \sum_{j=1}^n (B_{t_j} - B_{t_{j-1}})^2
\]
\[
= \frac{1}{2} B_T^2 - \frac{1}{2} T. \tag{15}
\]
If \( x_t \) is a continuously differentiable function such that \( x_0 = 0 \), we know that
\[
\int_0^T x_t \, dx_t = \int_0^T x_t x'_t \, dt = \frac{1}{2} x_T^2.
\]
Notice that in the case of Brownian motion an additional term appears: \( -\frac{1}{2} T \).

**Example 2** Consider a deterministic function \( g \) such that \( \int_0^T g(s)^2 \, ds < \infty \). The stochastic integral \( \int_0^T g_s \, dB_s \) is a normal random variable with law
\[
N(0, \int_0^T g(s)^2 \, ds).
\]

**Example 3** Let \( \{ B_t, t \geq 0 \} \) be a \( d \)-dimensional Brownian motion. That is, the components \( \{ B^k_t, t \geq 0 \}, k = 1, \ldots, d \) are independent Brownian motions. Denote by \( \mathcal{F}^{(d)}_t \) the filtration generated by \( B_t \) and the sets of probability zero. Then, each component \( B^k \) is an \( \mathcal{F}^{(d)}_t \)-Brownian motion although \( \mathcal{F}^{(d)}_t \) is not the filtration generated by \( B^k \). We can in this way consider stochastic integrals of the form
\[
\int_0^T B_2(s) \, dB_1^1(s),
\]
\[
\int_0^T \sin(B_2^2(s) + B_1^1(s)) \, dB_2(s).
\]

### 3.4 Indefinite Stochastic Integrals

Consider a stochastic process \( u \) in the space \( L^2_{a,T} \). Then, for any \( t \in [0,T] \) the process \( u_1_{[0,t]} \) also belongs to \( L^2_{a,T} \), and we can define its stochastic integral:
\[
\int_0^t u_s \, dB_s := \int_0^T u_s 1_{[0,t]}(s) \, dB_s.
\]
In this way we have constructed a new stochastic process
\[
\left\{ \int_0^t u_s \, dB_s, 0 \leq t \leq T \right\}
\]
which is the indefinite integral of $u$ with respect to $B$.

Properties of the indefinite integrals:

1. **Additivity**: For any $a \leq b \leq c$ we have
   \[
   \int_a^b u_s dB_s + \int_b^c u_s dB_s = \int_a^c u_s dB_s.
   \]

2. **Factorization**: If $a < b$ and $A$ is an event of the $\sigma$-field $\mathcal{F}_a$ then,
   \[
   \int_a^b 1_A u_s dB_s = 1_A \int_a^b u_s dB_s.
   \]
   Actually, this property holds replacing $1_A$ by any bounded and $\mathcal{F}_a$-measurable random variable.

3. **Martingale property**: The indefinite stochastic integral $M_t = \int_0^t u_s dB_s$ of a process $u \in L^2_{a,T}$ is a martingale with respect to the filtration $\mathcal{F}_t$.

   **Proof of the martingale property**: Consider a sequence $u^{(n)}$ of simple processes such that
   \[
   \lim_{n \to \infty} E \left( \int_0^T \left| u_t - u^{(n)}_t \right|^2 dt \right) = 0.
   \]
   Set $M_n(t) = \int_0^t u^{(n)}_s dB_s$. If $\phi_j$ is the value of the simple stochastic process $u^{(n)}$ on each interval $(t_{j-1}, t_j]$, $j = 1, \ldots, n$ and $s \leq t_k \leq t_{m-1} \leq t$ we have
   \[
   E(M_n(t) - M_n(s)|\mathcal{F}_s) = E \left( \phi_k (B_{t_k} - B_s) + \sum_{j=k+1}^{m-1} \phi_j \Delta B_j + \phi_m (B_t - B_{t_{m-1}})|\mathcal{F}_s \right).
   \]
   \[
   = E(\phi_k (B_{t_k} - B_s)|\mathcal{F}_s) + \sum_{j=k+1}^{m-1} E \left( E \left( \phi_j \Delta B_j |\mathcal{F}_{t_{j-1}} \right) |\mathcal{F}_s \right) + E \left( E \left( \phi_m (B_t - B_{t_{m-1}}) |\mathcal{F}_{t_{m-1}} \right) |\mathcal{F}_s \right)
   \]
   \[
   = \phi_k E((B_{t_k} - B_s)|\mathcal{F}_s) + \sum_{j=k+1}^{m-1} \phi_j E(\Delta B_j |\mathcal{F}_{t_{j-1}}) |\mathcal{F}_s) + \phi_m E((B_t - B_{t_{m-1}}) |\mathcal{F}_{t_{m-1}}) |\mathcal{F}_s)
   \]
   \[
   = 0.
   \]

   Finally, the result follows from the fact that the convergence in mean square $M_n(t) \to M_t$ implies the convergence in mean square of the conditional expectations. □
4. **Continuity:** Suppose that \( u \) belongs to the space \( L^2_{a,T} \). Then, the stochastic integral \( M_t = \int_0^t u_s dB_s \) has a version with continuous trajectories.

**Proof of continuity:** With the same notation as above, the process \( M_n \) is a martingale with continuous trajectories. Then, Doob’s maximal inequality applied to the continuous martingale \( M_n - M_m \) with \( p = 2 \) yields

\[
P \left( \sup_{0 \leq t \leq T} |M_n(t) - M_m(t)| > \lambda \right) \leq \frac{1}{\lambda^2} \mathbb{E} \left( |M_n(T) - M_m(T)|^2 \right)
\]

\[
= \frac{1}{\lambda^2} \mathbb{E} \left( \int_0^T |u_n(t) - u_m(t)|^2 \, dt \right) \xrightarrow{n,m \to \infty} 0.
\]

We can choose an increasing sequence of natural numbers \( n_k, k = 1, 2, \ldots \) such that

\[
P \left( \sup_{0 \leq t \leq T} |M_{n_{k+1}}(t) - M_{n_k}(t)| > 2^{-k} \right) \leq 2^{-k}.
\]

The events \( A_k := \{ \sup_{0 \leq t \leq T} |M_{n_{k+1}}(t) - M_{n_k}(t)| > 2^{-k} \} \) verify

\[
\sum_{k=1}^{\infty} P(A_k) < \infty.
\]

Hence, Borel-Cantelli lemma implies that \( P(\limsup_k A_k) = 0 \), or

\[
P(\liminf_k A_k^c) = 1.
\]

That means, there exists a set \( N \) of probability zero such that for all \( \omega \notin N \) there exists \( k_1(\omega) \) such that for all \( k \geq k_1(\omega) \)

\[
\sup_{0 \leq t \leq T} |M_{n_{k+1}}(t, \omega) - M_{n_k}(t, \omega)| \leq 2^{-k}.
\]

As a consequence, if \( \omega \notin N \), the sequence \( M_{n_k}(t, \omega) \) is uniformly convergent on \([0, T]\) to a continuous function \( J_t(\omega) \). On the other hand, we know that for any \( t \in [0, T] \), \( M_{n_k}(t) \) converges in mean square to \( \int_0^t u_s dB_s \). So, \( J_t(\omega) = \int_0^t u_s dB_s \) almost surely, for all \( t \in [0, T] \), and we have proved that the indefinite stochastic integral possesses a continuous version. □

5. **Maximal inequality for the indefinite integral:** \( M_t = \int_0^t u_s dB_s \) of a processes \( u \in L^2_{a,T} \): For all \( \lambda > 0 \),

\[
P \left( \sup_{0 \leq t \leq T} |M_t| > \lambda \right) \leq \frac{1}{\lambda^2} \mathbb{E} \left( \int_0^T u_s^2 \, dt \right).
\]
6. Stochastic integration up to a stopping time: If \( u \) belongs to the space \( L^2_{a,T} \) and \( \tau \) is a stopping time bounded by \( T \), then the process \( u1_{[0,\tau]} \) also belongs to \( L^2_{a,T} \) and we have:

\[
\int_0^T u_t 1_{[0,\tau]}(t)dB_t = \int_0^\tau u_t dB_t.
\]

**Proof of (16):** The proof will be done in two steps:

(a) Suppose first that the process \( u \) has the form \( u_t = F_{1_{(a,b)}(t)} \), where \( 0 \leq a < b \leq T \) and \( F \in L^2(\Omega, \mathcal{F}_a, P) \). The stopping times \( \tau_n = \sum_{i=1}^{2^n} t^n_i \cdot 1_{A^n_i} \), where \( t^n_i = \frac{iT}{2^n} \), \( A^n_i = \left\{ \frac{(i-1)T}{2^n} \leq \tau < \frac{iT}{2^n} \right\} \) form a nonincreasing sequence which converges to \( \tau \). For any \( n \) we have

\[
\int_0^{\tau_n} u_t dB_t = F(\mathcal{B}_{b\wedge \tau_n} - \mathcal{B}_{a\wedge \tau_n}).
\]

On the other hand,

\[
\int_0^T u_t 1_{[0,\tau_n]}(t)dB_t = \sum_{i=1}^{2^n} \int_0^T 1_{A^n_i} 1_{[0,t^n_i]}(t)u_t dB_t
\]

\[
= \sum_{i=1}^{2^n} \int_0^T 1_{B^n_i} 1_{(t^{i-1}_n,t^n_i)}(t)u_t dB_t,
\]

where \( B^n_i = A^n_i \cup A^{n+1}_i \cup \ldots \cup A^{2^n}_i \). The process \( 1_{B^n_i} 1_{(t^{i-1}_n,t^n_i)}(t) \) is simple because \( B^n_i = \left\{ \frac{(i-1)T}{2^n} \leq \tau \right\} \in \mathcal{F}_{t^{i-1}_n} \). As a consequence,

\[
\int_0^T u_t 1_{[0,\tau_n]}(t)dB_t = \sum_{i=1}^{2^n} \int_0^T 1_{B^n_i} 1_{(a,b)\cap(t^{i-1}_n,t^n_i)}(t)F dB_t
\]

\[
= F \sum_{i=1}^{2^n} \int_0^T 1_{B^n_i} 1_{(a,b)\cap(t^{i-1}_n,t^n_i)}(t)dB_t
\]

\[
= F \sum_{i=1}^{2^n} 1_{A^n_i} \int_0^T 1_{(a,b)\cap[0,t^n_i]}(t)dB_t
\]

\[
= \sum_{i=1}^{2^n} 1_{A^n_i} F(\mathcal{B}_{b\wedge t^n_i} - \mathcal{B}_{a\wedge t^n_i})
\]

\[
= F(\mathcal{B}_{b\wedge \tau_n} - \mathcal{B}_{a\wedge \tau_n}).
\]

Taking the limit as \( n \) tends to infinity we deduce the equality in the case of a simple process.

(b) In the general case, it suffices to approximate the process \( u \) by simple processes. The convergence of the right-hand side of (16) follows from Doob’s maximal inequality. \( \square \)
7. **Quadratic variation:** The martingale $M_t = \int_0^t u_s dB_s$ has a nonzero quadratic variation, like the Brownian motion, and we have

$$\langle M \rangle_t = \int_0^t u_s^2 ds.$$

### 3.5 Extension of the Stochastic Integral

Ito’s stochastic integral $\int_0^T u_s dB_s$ can be defined for classes of processes larger than $L^2_{a,T}$. We can replace $E \left( \int_0^T u_t^2 dt \right) < \infty$ by the weaker assumption $P \left( \int_0^T u_t^2 dt < \infty \right) = 1$. We denote by $L_{a,T}$ the space of predictable processes such that $\int_0^T u_t^2 dt < \infty$, almost surely. Then, the stochastic integral is extended to the space $L_{a,T}$ by means of a localization argument.

Suppose that $u$ belongs to $L_{a,T}$. For each $n \geq 1$ we define the stopping time

$$\tau_n = \inf \left\{ t \geq 0 : \int_0^t u_s^2 ds = n \right\},$$

(17)

where, by convention, $\tau_n = T$ if $\int_0^T u_t^2 dt < n$. In this way we obtain a nondecreasing sequence of stopping times such that $\tau_n \uparrow T$. Furthermore,

$$t < \tau_n \iff \int_0^t u_s^2 ds < n.$$

Set

$$u^{(n)}_t = u_t 1_{(0, \tau_n)}(t).$$

The process $u^{(n)} = \{ u^{(n)}_t, 0 \leq t \leq T \}$ belongs to $L^2_{a,T}$ since $E \left( \int_0^T \left( u^{(n)}_s \right)^2 ds \right) \leq n$. If $n \leq m$, on the set $\{ t \leq \tau_n \}$ we have

$$\int_0^t u^{(n)}_s dB_s = \int_0^t u^{(m)}_s dB_s,$$

because by (16) we can write

$$\int_0^t u^{(n)}_s dB_s = \int_0^t u^{(m)}_s 1_{(0, \tau_n)}(s) dB_s = \int_0^{\tau_n} u^{(m)}_s dB_s.$$

As a consequence, there exists an adapted and continuous process denoted by $\int_0^t u_s dB_s$ such that for any $n \geq 1$,

$$\int_0^t u^{(n)}_s dB_s = \int_0^t u_s dB_s$$

if $t \leq \tau_n$.

The stochastic integral of processes in the space $L_{a,T}$ is linear and has continuous trajectories. However, it may have infinite expectation and variance. Instead of the isometry property, there is a continuity property in probability as it follows from the next proposition:
Proposition 23 Suppose that $u \in L_{a,T}$. For all $K, \delta > 0$ we have:

$$P\left(\left|\int_0^T u_s dB_s\right| \geq K\right) \leq P\left(\int_0^T u_s^2 ds \geq \delta\right) + \frac{\delta}{K^2}.$$

\textbf{Proof.} Consider the stopping time defined by

$$\tau = \inf \left\{ t \geq 0 : \int_0^t u_s^2 ds = \delta \right\},$$

with the convention that $\tau = T$ if $\int_0^T u_s^2 ds < \delta$. We have

$$P\left(\left|\int_0^T u_s dB_s\right| \geq K\right) \leq P\left(\int_0^T u_s^2 ds \geq \delta\right) + P\left(\left|\int_0^T u_s dB_s\right| \geq K, \int_0^T u_s^2 ds < \delta\right),$$

and on the other hand,

$$P\left(\left|\int_0^T u_s dB_s\right| \geq K, \int_0^T u_s^2 ds < \delta\right) = P\left(\left|\int_0^\tau u_s dB_s\right| \geq K, \tau = T\right) \leq P\left(\left|\int_0^\tau u_s dB_s\right| \geq K\right) \leq \frac{1}{K^2} E\left(\left|\int_0^\tau u_s dB_s\right|^2\right) = \frac{1}{K^2} E\left(\int_0^\tau u_s^2 ds\right) \leq \frac{\delta}{K^2}.$$

As a consequence of the above proposition, if $u^{(n)}$ is a sequence of processes in the space $L_{a,T}$ which converges to $u \in L_{a,T}$ in probability:

$$P\left(\sup_{t \in [0, T]} \left|\int_0^t \left(u_s^{(n)} - u_s\right)^2 ds\right| > \epsilon \right) \xrightarrow{n \to \infty} 0, \text{ for all } \epsilon > 0$$

then,

$$\int_0^T u_s^{(n)} dB_s \xrightarrow{P} \int_0^T u_s dB_s.$$

The indefinite integral $\int_0^T u_s dB_s$ is a continuous local martingale. This means, that there exists an increasing sequence of stopping times $\tau_n$ such that $\tau \uparrow T$, and for each $n \geq 1$, $\left\{\int_0^{\tau_n} u_s dB_s, t \in [0, T]\right\}$ is a martingale.
3.6 Itô’s Formula

Itô’s formula is the stochastic version of the chain rule of the ordinary differential calculus. Consider the following example

\[ \int_0^t B_s dB_s = \frac{1}{2}B_t^2 - \frac{1}{2}t, \]

that can be written as

\[ B_t^2 = \int_0^t 2B_s dB_s + t, \]

or in differential notation

\[ d(B_t^2) = 2B_t dB_t + dt. \]

Formally, this follows from Taylor development of \( B_t^2 \) as a function of \( t \), with the convention \((dB_t)^2 = dt\).

The stochastic process \( B_t^2 \) can be expressed as the sum of an indefinite stochastic integral \( \int_0^t 2B_s dB_s \), plus a differentiable function. More generally, we will see that any process of the form \( f(B_t) \), where \( f \) is twice continuously differentiable, can be expressed as the sum of an indefinite stochastic integral, plus a process with differentiable trajectories. This leads to the definition of Itô processes.

Denote by \( L_{a,T}^1 \) the space of predictable processes \( v \) which satisfy \( P\left( \int_0^T |v_t| \, dt < \infty \right) = 1 \).

**Definition 24** A continuous and adapted stochastic process \( \{X_t, 0 \leq t \leq T\} \) is called an Itô process if it can be expressed in the form

\[ X_t = X_0 + \int_0^t u_s dB_s + \int_0^t v_s ds, \quad (18) \]

where \( u \) belongs to the space \( L_{a,T}^1 \) and \( v \) belongs to the space \( L_{a,T}^1 \).

In differential notation we will write

\[ dX_t = u_t dB_t + v_t dt. \]

**Theorem 25 (Itô’s formula)** Suppose that \( X \) is an Itô process of the form (18). Let \( f(t, x) \) be a function twice differentiable with respect to the variable \( x \) and once differentiable with respect to \( t \), with continuous partial derivatives \( \frac{\partial f}{\partial t} \), \( \frac{\partial^2 f}{\partial x^2} \), and \( \frac{\partial f}{\partial x} \) (we say that \( f \) is of class \( C^{1,2} \)). Then, the process \( Y_t = f(t, X_t) \) is again an Itô process with the representation

\[ Y_t = f(0, X_0) + \int_0^t \frac{\partial f}{\partial t}(s, X_s) ds + \int_0^t \frac{\partial f}{\partial x}(s, X_s) u_s dB_s \\
+ \int_0^t \frac{\partial^2 f}{\partial x^2}(s, X_s) v_s ds + \frac{1}{2} \int_0^t \frac{\partial^2 f}{\partial x^2}(s, X_s) u_s^2 ds. \]
1.- In differential notation Itô’s formula can be written as
\[ df(t, X_t) = \frac{\partial f}{\partial t}(t, X_t)dt + \frac{\partial f}{\partial x}(t, X_t)dX_t + \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s, X_s)(dX_t)^2, \]
where \((dX_t)^2\) is computed using the product rule
\[
\begin{array}{c|c|c}
\times & dB_t & dt \\
\hline
dB_t & dt & 0 \\
\hline
dt & 0 & 0
\end{array}
\]

2.- The process \(Y_t\) is an Itô process with the representation
\[ Y_t = Y_0 + \int_0^t \tilde{u}_s dB_s + \int_0^t \tilde{v}_s ds, \]
where
\[
Y_0 = f(0, X_0),
\]
\[
\tilde{u}_t = \frac{\partial f}{\partial x}(t, X_t)u_t,
\]
\[
\tilde{v}_t = \frac{\partial f}{\partial t}(t, X_t) + \frac{\partial f}{\partial x}(t, X_t)v_t + \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(t, X_t)u_t^2.
\]
Notice that \(\tilde{u}_t \in L_{a,T}\) and \(\tilde{v}_t \in L^1_{a,T}\) due to the continuity of \(X\).

3.- In the particular case \(u_t = 1, v_t = 0, X_0 = 0\), the process \(X_t\) is the Brownian motion \(B_t\), and Itô’s formula has the following simple version
\[ f(t, B_t) = f(0, 0) + \int_0^t f'(X_s)u_s dB_s + \int_0^t f'(X_s)v_s ds + \frac{1}{2} \int_0^t f''(X_s)u_s^2 ds. \]

4.- In the particular case where \(f\) does not depend on the time we obtain the formula
\[ f(X_t) = f(0) + \int_0^t f'(X_s)u_s dB_s + \int_0^t f'(X_s)v_s ds + \frac{1}{2} \int_0^t f''(X_s)u_s^2 ds. \]

Itô’s formula follows from Taylor development up to the second order. We will explain the heuristic ideas that lead to Itô’s formula using Taylor development. Suppose \(v = 0\). Fix \(t > 0\) and consider the times \(t_j = \frac{j}{n}\). Taylor’s formula up to the second order gives
\[ f(X_t) - f(0) = \sum_{j=1}^n [f(X_{t_j}) - f(X_{t_{j-1}})]
= \sum_{j=1}^n f'(X_{t_{j-1}})\Delta X_j + \frac{1}{2} \sum_{j=1}^n f''(X_j)(\Delta X_j)^2, \quad (19) \]
where $\Delta X_j = X_{t_j} - X_{t_{j-1}}$ and $\overline{X}_j$ is an intermediate value between $X_{t_{j-1}}$ and $X_{t_j}$.

The first summand in the above expression converges in probability to $\int_0^t f'(X_s)u_s dB_s$, whereas the second summand converges in probability to $\frac{1}{2} \int_0^t f''(X_s)u_s^2 ds$.

Some examples of application of Itô’s formula:

**Example 4** If $f(x) = x^2$ and $X_t = B_t$, we obtain

$$B_t^2 = 2 \int_0^t B_s dB_s + t,$$

because $f'(x) = 2x$ and $f''(x) = 2$.

**Example 5** If $f(x) = x^3$ and $X_t = B_t$, we obtain

$$B_t^3 = 3 \int_0^t B_s^2 dB_s + 3 \int_0^t B_s ds,$$

because $f'(x) = 3x^2$ and $f''(x) = 6x$. More generally, if $n \geq 2$ is a natural number,

$$B_t^n = n \int_0^t B_s^{n-1} dB_s + \frac{n(n-1)}{2} \int_0^t B_s^{n-2} ds.$$

**Example 6** If $f(t, x) = e^{ax-x^2 t}$, $X_t = B_t$, and $Y_t = e^{aB_t-x^2 t}$, we obtain

$$Y_t = 1 + a \int_0^t Y_s dB_s$$

because

$$\frac{\partial f}{\partial t} + \frac{1}{2} \frac{\partial^2 f}{\partial x^2} = 0. \quad (20)$$

This important example leads to the following remarks:

1. - If a function $f(t, x)$ of class $C^{1,2}$ satisfies the equality (20), then, the stochastic process $f(t, B_t)$ will be an indefinite integral plus a constant term. Therefore, $f(t, B_t)$ will be a martingale provided $f$ satisfies:

$$E \left[ \int_0^t \left( \frac{\partial f}{\partial x} (s, B_s) \right)^2 ds \right] < \infty$$

for all $t \geq 0$.

2. - The solution of the stochastic differential equation

$$dY_t = aY_t dB_t$$

is not $Y_t = e^{aB_t}$, but $Y_t = e^{aB_t-x^2 t}$. 54
Example 7 Suppose that $f(t)$ is a continuously differentiable function on $[0, T]$. Itô’s formula applied to the function $f(t)x$ yields

$$f(t)B_t = \int_0^t f_s dB_s + \int_0^t B_s f'_s ds$$

and we obtain the integration by parts formula

$$\int_0^t f_s dB_s = f(t)B_t - \int_0^t B_s f'_s ds.$$

We are going to present a multidimensional version of Itô’s formula. Suppose that $B_t = (B^1_t, B^2_t, \ldots, B^m_t)$ is an $m$-dimensional Brownian motion. Consider an $n$-dimensional Itô process of the form

$$\begin{cases} 
X^1_t = X^1_0 + \int_0^t u^{11}_s dB^1_s + \cdots + \int_0^t u^{1m}_s dB^m_s + \int_0^t v^1_s ds \\
\vdots \\
X^n_t = X^n_0 + \int_0^t u^{n1}_s dB^1_s + \cdots + \int_0^t u^{nm}_s dB^m_s + \int_0^t v^n_s ds
\end{cases}.$$

In differential notation we can write

$$dX^i_t = \sum_{l=1}^m u^{il}_t dB^l_t + v^i_t dt$$
or

$$dX^i_t = u^i_t dB^i_t + v^i_t dt.$$

where $v_t$ is an $n$-dimensional process and $u_t$ is a process with values in the set of $n \times m$ matrices and we assume that the components of $u$ belong to $L_{a,T}$ and those of $v$ belong to $L^1_{a,T}$.

Then, if $f : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^p$ is a function of class $C^{1,2}$, the process $Y_t = f(t, X_t)$ is again an Itô process with the representation

$$dY^k_t = \frac{\partial f_k}{\partial t}(t, X_t) dt + \sum_{i=1}^n \frac{\partial f_k}{\partial x^i}(t, X_t) dX^i_t + \frac{1}{2} \sum_{i,j=1}^n \frac{\partial^2 f_k}{\partial x^i \partial x^j}(t, X_t) dX^i_t dX^j_t.$$

The product of differentials $dX^i_t dX^j_t$ is computed by means of the product rules:

$$dB^i_t dB^j_t = \begin{cases} 
0 & \text{if } i \neq j \\
(dt) & \text{if } i = j
\end{cases}$$

$$(dt)^2 = 0.$$
In this way we obtain

\[ dX_i^t dX_j^t = \left( \sum_{k=1}^m u_{ik} u_{jk} \right) dt = (u_t u'_t)_{ij} dt. \]

As a consequence we can deduce the following integration by parts formula: Suppose that \( X_t \) and \( Y_t \) are Itô processes. Then,

\[ X_t Y_t = X_0 Y_0 + \int_0^t X_s dY_s + \int_0^t Y_s dX_s + \int_0^t dX_s dY_s. \]

### 3.7 Itô’s Integral Representation

Consider a process \( u \) in the space \( L^2_{a,T} \). We know that the indefinite stochastic integral

\[ X_t = \int_0^t u_s dB_s \]

is a martingale with respect to the filtration \( \mathcal{F}_t \). The aim of this subsection is to show that any square integrable martingale is of this form. We start with the integral representation of square integrable random variables.

**Theorem 26 (Itô’s integral representation)** Consider a random variable \( F \) in \( L^2(\Omega, \mathcal{F}_T, P) \). Then, there exists a unique process \( u \) in the space \( L^2_{a,T} \) such that

\[ F = E(F) + \int_0^T u_s dB_s. \]

**Proof.** Suppose first that \( F \) is of the form

\[ F = \exp \left( \int_0^T h_s dB_s - \frac{1}{2} \int_0^T h_s^2 ds \right), \quad (21) \]

where \( h \) is a deterministic function such that \( \int_0^T h_s^2 ds < \infty \). Define

\[ Y_t = \exp \left( \int_0^t h_s dB_s - \frac{1}{2} \int_0^t h_s^2 ds \right). \]

By Itô’s formula applied to the function \( f(x) = e^x \) and the process \( X_t = \int_0^t h_s dB_s - \frac{1}{2} \int_0^t h_s^2 ds \), we obtain

\[ dY_t = Y_t \left( h(t) dB_t - \frac{1}{2} h^2(t) dt \right) + \frac{1}{2} Y_t (h(t) dB_t)^2 \]

that is,

\[ Y_t = 1 + \int_0^t Y_s h(s) dB_s. \]
Hence,

\[ F = Y_T = 1 + \int_0^T Y_s h(s) dB_s \]

and we get the desired representation because \( E(F) = 1 \),

\[
E \left( \int_0^T Y_s^2 h_s^2(s) ds \right) = \int_0^T E(Y_s^2) h_s^2(s) ds \\
= \int_0^T e^{\int_0^s h_s^2(s) ds} \left( \int_0^s h_s^2(s) ds \right) ds \\
\leq \exp \left( \int_0^T h_s^2(s) ds \right) \int_0^T h_s^2(s) ds < \infty.
\]

By linearity, the representation holds for linear combinations of exponentials of the form (21). In the general case, any random variable \( F \) in \( L^2(\Omega, F_T, P) \) can be approximated in mean square by a sequence \( F_n \) of linear combinations of exponentials of the form (21). Then, we have

\[ F_n = E(F_n) + \int_0^T u_s^{(n)} dB_s. \]

By the isometry of the stochastic integral

\[
E \left[ (F_n - F_m)^2 \right] = E \left[ \left( E(F_n - F_m) + \int_0^T (u_s^{(n)} - u_s^{(m)}) dB_s \right)^2 \right] \\
= (E(F_n - F_m))^2 + E \left[ \left( \int_0^T (u_s^{(n)} - u_s^{(m)}) dB_s \right)^2 \right] \\
\geq E \left[ \int_0^T (u_s^{(n)} - u_s^{(m)})^2 ds \right].
\]

The sequence \( F_n \) is a Cauchy sequence in \( L^2(\Omega, F_T, P) \). Hence,

\[ E \left[ (F_n - F_m)^2 \right] \overset{n,m \to \infty}{\longrightarrow} 0 \]

and, therefore,

\[ E \left[ \int_0^T (u_s^{(n)} - u_s^{(m)})^2 ds \right] \overset{n,m \to \infty}{\longrightarrow} 0. \]

This means that \( u^{(n)} \) is a Cauchy sequence in \( L^2([0, T) \times \Omega) \). Consequently, it will converge to a process \( u \) in \( L^2([0, T] \times \Omega) \). We can show that the process \( u \), as an element of \( L^2([0, T] \times \Omega) \) has a version which is predictable, because there exists a subsequence \( u^{(n)}(t, \omega) \) which converges to \( u(t, \omega) \) for almost all \((t, \omega)\).
So, \( u \in L^2_{a,T} \). Applying again the isometry property, and taking into account that \( E(F_n) \) converges to \( E(F) \), we obtain

\[
F = \lim_{n \to \infty} F_n = \lim_{n \to \infty} \left( E(F) + \int_0^T u_s^{(n)} dB_s \right) = E(F) + \int_0^T u_s dB_s.
\]

Finally, uniqueness also follows from the isometry property: Suppose that \( u^{(1)} \) and \( u^{(2)} \) are processes in \( L^2_{a,T} \) such that

\[
F = E(F) + \int_0^T u_s^{(1)} dB_s = E(F) + \int_0^T u_s^{(2)} dB_s.
\]

Then

\[
0 = E \left[ \left( \int_0^T (u_s^{(1)} - u_s^{(2)}) dB_s \right)^2 \right] = E \left[ \int_0^T (u_s^{(1)} - u_s^{(2)})^2 ds \right]
\]

and, hence, \( u_s^{(1)}(t, \omega) = u_s^{(2)}(t, \omega) \) for almost all \((t, \omega)\).

**Theorem 27 (Martingale representation theorem)** Suppose that \( \{M_t, t \in [0, T]\} \) is a martingale with respect to the \( \mathcal{F}_t \), such that \( E(M_T^2) < \infty \). Then there exists a unique stochastic process \( u \) in the space \( L^2_{a,T} \) such that

\[
M_t = E(M_0) + \int_0^t u_s dB_s
\]

for all \( t \in [0, T] \).

**Proof.** Applying Itô’s representation theorem to the random variable \( F = M_T \) we obtain a unique process \( u \in L^2_{a,T} \) such that

\[
M_T = E(M_T) + \int_0^T u_s dB_s = E(M_0) + \int_0^T u_s dB_s.
\]

Suppose \( 0 \leq t \leq T \). We obtain

\[
M_t = E[M_T | \mathcal{F}_t] = E(M_0) + E[\int_0^T u_s dB_s | \mathcal{F}_t]
\]

\[
= E(M_0) + \int_0^t u_s dB_s.
\]

**Example 8** We want to find the integral representation of \( F = B_T^3 \). By Itô’s formula

\[
B_T^3 = \int_0^T 3B_t^2 dB_t + 3 \int_0^T B_t dt,
\]

58
and integrating by parts

\[ \int_0^T B_t \, dt = TB_T - \int_0^T t \, dB_t = \int_0^T (T-t) \, dB_t. \]

So, we obtain the representation

\[ B^3_T = \int_0^T 3 \left[ B^2_t + (T-t) \right] \, dB_t. \]

### 3.8 Girsanov Theorem

Girsanov theorem says that a Brownian motion with drift \( B_t + \lambda t \) can be seen as a Brownian motion without drift, with a change of probability. We first discuss changes of probability by means of densities.

Suppose that \( L \geq 0 \) is a nonnegative random variable on a probability space \( (\Omega, \mathcal{F}, P) \) such that \( E(L) = 1 \). Then,

\[ Q(A) = E(1_A L) \]

defines a new probability. In fact, \( Q \) is a \( \sigma \)-additive measure such that

\[ Q(\Omega) = E(L) = 1. \]

We say that \( L \) is the **density** of \( Q \) with respect to \( P \) and we write

\[ \frac{dQ}{dP} = L. \]

The expectation of a random variable \( X \) in the probability space \( (\Omega, \mathcal{F}, Q) \) is computed by the formula

\[ E_Q(X) = E(XL). \]

The probability \( Q \) is absolutely continuous with respect to \( P \), that means,

\[ P(A) = 0 \implies Q(A) = 0. \]

If \( L \) is strictly positive, then the probabilities \( P \) and \( Q \) are **equivalent** (that is, mutually absolutely continuous), that means,

\[ P(A) = 0 \iff Q(A) = 0. \]

The next example is a simple version of Girsanov theorem.

**Example 9** Let \( X \) be a random variable with distribution \( N(m, \sigma^2) \). Consider the random variable

\[ L = e^{-\frac{m}{\sigma^2} X + \frac{m^2}{2\sigma^2}}. \]
which satisfies $E(L) = 1$. Suppose that $Q$ has density $L$ with respect to $P$. On the probability space $(\Omega, \mathcal{F}, Q)$ the variable $X$ has the characteristic function:

$$E_Q(e^{itX}) = E(e^{itX}) = \frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{\infty} e^{-(x-m)^2/(2\sigma^2)} e^{itx} dx = \frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{\infty} e^{-x^2/(2\sigma^2)} e^{itx} dx = e^{-\frac{t^2\sigma^2}{2}}.$$

so, $X$ has distribution $N(0, \sigma^2)$.

Let $\{B_t, t \in [0, T]\}$ be a Brownian motion. Fix a real number $\lambda$ and consider the martingale

$$L_t = \exp\left(-\lambda B_t - \frac{\lambda^2}{2} t\right). \quad (22)$$

We know that the process $\{L_t, t \in [0, T]\}$ is a positive martingale with expectation 1 which satisfies the linear stochastic differential equation

$$L_t = 1 - \int_0^t \lambda L_s dB_s.$$ 

The random variable $L_T$ is a density in the probability space $(\Omega, \mathcal{F}_T, P)$ which defines a probability $Q$ given by

$$Q(A) = E(1_A L_T),$$

for all $A \in \mathcal{F}_T$.

The martingale property of the process $L_t$ implies that, for any $t \in [0, T]$, in the space $(\Omega, \mathcal{F}_t, P)$, the probability $Q$ has density $L_t$ with respect to $P$. In fact, if $A$ belongs to the $\sigma$-field $\mathcal{F}_t$ we have

$$Q(A) = E(1_A L_T) = E(E(1_A L_T | \mathcal{F}_t)) = E(1_A E(L_T | \mathcal{F}_t)) = E(1_A L_t).$$

**Theorem 28 (Girsanov theorem)** In the probability space $(\Omega, \mathcal{F}_T, Q)$ the stochastic process

$$W_t = B_t + \lambda t,$$

is a Brownian motion.

In order to prove Girsanov theorem we need the following technical result:

**Lemma 29** Suppose that $X$ is a real random variable and $\mathcal{G}$ is a $\sigma$-field such that

$$E\left( e^{iuX} | \mathcal{G} \right) = e^{-\frac{u^2\sigma^2}{2}}.$$

Then, the random variable $X$ is independent of the $\sigma$-field $\mathcal{G}$ and it has the normal distribution $N(0, \sigma^2)$.  

60
Proof. For any $A \in \mathcal{G}$ we have

$$E \left( 1_A e^{iuX} \right) = P(A) e^{- \frac{u^2 \sigma^2}{2}}.$$  

Thus, choosing $A = \Omega$ we obtain that the characteristic function of $X$ is that of a normal distribution $N(0, \sigma^2)$. On the other hand, for any $A \in \mathcal{G}$, the characteristic function of $X$ with respect to the conditional probability given $A$ is again that of a normal distribution $N(0, \sigma^2)$:

$$E_A \left( e^{iuX} \right) = e^{- \frac{u^2 \sigma^2}{2}}.$$  

That is, the law of $X$ given $A$ is again a normal distribution $N(0, \sigma^2)$:

$$P_A(X \leq x) = \Phi \left( \frac{x}{\sigma} \right),$$

where $\Phi$ is the distribution function of the law $N(0, 1)$. Thus,

$$P((X \leq x) \cap A) = P(A)\Phi(x/\sigma) = P(A)P(X \leq x),$$

and this implies the independence of $X$ and $\mathcal{G}$.

Proof of Girsanov theorem. It is enough to show that in the probability space $(\Omega, \mathcal{F}_T, Q)$, for all $s < t \leq T$ the increment $W_t - W_s$ is independent of $\mathcal{F}_s$ and has the normal distribution $N(0, t - s)$.

Taking into account the previous lemma, these properties follow from the following relation, for all $s < t$, $A \in \mathcal{F}_s$, $u \in \mathbb{R}$,

$$E_Q \left( 1_A e^{iu(W_t - W_s)} \right) = Q(A) e^{- \frac{u^2}{2}(t-s)}. \quad (23)$$

In order to show (23) we write

$$E_Q \left( 1_A e^{iu(W_t - W_s)} \right) = E \left( 1_A e^{iu(W_t - W_s)} L_t \right)$$

$$= E \left( 1_A e^{iu(B_t - B_s) + iu\lambda(t-s) - \lambda(B_t - B_s) - \frac{\lambda^2}{2}(t-s) L_s} \right)$$

$$= E (1_A L_s) E \left( e^{iu\lambda(B_t - B_s)} \right) e^{iu\lambda(t-s) - \frac{\lambda^2}{2}(t-s)}$$

$$= Q(A) e^{ \frac{(iu - \lambda)(t-s)}{2} + iu\lambda(t-s) - \frac{\lambda^2}{2}(t-s)}$$

$$= Q(A) e^{- \frac{u^2}{2}(t-s)}.$$  

Girsanov theorem admits the following generalization:

**Theorem 30** Let $\{\theta_t, t \in [0, T]\}$ be a predictable process such that it satisfies the following Novikov condition:

$$E \left( \exp \left( \frac{1}{2} \int_0^T \theta_t^2 \, dt \right) \right) < \infty.$$  

(24)
Then, the process
\[ W_t = B_t + \int_0^t \theta_s ds \]
is a Brownian motion with respect to the probability \( Q \) defined by
\[ Q(A) = E(1_A L_T), \]
where
\[ L_t = \exp \left(- \int_0^t \theta_s dB_s - \frac{1}{2} \int_0^t \theta_s^2 ds \right). \]

Notice that again \( L_t \) satisfies the linear stochastic differential equation
\[ L_t = 1 - \int_0^t \theta_s L_s dB_s. \]

For the process \( L_t \) to be a density we need \( E(L_t) = 1 \), and condition (24) ensures this property.

As an application of Girsanov theorem we will compute the probability distribution of the hitting time of a level \( a \) by a Brownian motion with drift.

Let \( \{ B_t, t \geq 0 \} \) be a Brownian motion. Fix a real number \( \lambda \), and define
\[ L_t = \exp \left( - \lambda B_t - \frac{\lambda^2}{2} t \right). \]

Let \( Q \) be the probability on each \( \sigma \)-field \( F_t \) such that for all \( t > 0 \)
\[ \frac{dQ}{dP}|_{F_t} = L_t. \]

By Girsanov theorem, for all \( T > 0 \), in the probability space \( (\Omega, F_T, Q) \) the process \( B_t + \lambda t := \tilde{B}_t \) is a Brownian motion in the time interval \([0, T]\). That is, in this space \( B_t \) is a Brownian motion with drift \(-\lambda t\). Set
\[ \tau_a = \inf \{ t \geq 0, B_t = a \}, \]
where \( a \neq 0 \). For any \( t \geq 0 \) the event \( \{ \tau_a \leq t \} \) belongs to the \( \sigma \)-field \( F_{\tau_a \wedge t} \) because for any \( s \geq 0 \)
\[ \{ \tau_a \leq t \} \cap \{ \tau_a \wedge t \leq s \} = \{ \tau_a \leq t \} \cap \{ \tau_a \leq s \}\]
\[ = \{ \tau_a \leq t \wedge s \} \in F_{\tau_a \wedge t} \subset F_s. \]

Consequently, using the Optional Stopping Theorem we obtain
\[ Q\{ \tau_a \leq t \} = E(1_{\{ \tau_a \leq t \}} L_t) = E(1_{\{ \tau_a \leq t \}} E(L_t \mid F_{\tau_a \wedge t})) = E(1_{\{ \tau_a \leq t \}} L_{\tau_a \wedge t}) = E(1_{\{ \tau_a \leq t \}} e^{-\lambda a - \frac{1}{2} \lambda^2 \tau_a}) = \int_0^t e^{-\lambda a - \frac{1}{2} \lambda^2 s} f(s) ds, \]
where \( f \) is the density of the random variable \( \tau_a \). We know that
\[
f(s) = \frac{|a|}{\sqrt{2\pi s^3}} e^{-\frac{s^2}{2}}.
\]
Hence, with respect to \( Q \) the random variable \( \tau_a \) has the probability density
\[
\frac{|a|}{\sqrt{2\pi s^3}} e^{-\frac{(s+\lambda a)^2}{2}}, \quad s > 0.
\]
Letting, \( t \uparrow \infty \) we obtain
\[
Q\{\tau_a < \infty\} = e^{-\lambda a} E\left(e^{-\frac{1}{2}\lambda^2 \tau_a}\right) = e^{-\lambda a - |\lambda a|}.
\]
If \( \lambda = 0 \) (Brownian motion without drift), the probability to reach the level is one. If \( -\lambda a > 0 \) (the drift \(-\lambda\) and the level \(a\) have the same sign) this probability is also one. If \( -\lambda a < 0 \) (the drift \(-\lambda\) and the level \(a\) have opposite sign) this probability is \( e^{-2\lambda a}\).

**Exercises**

3.1 Let \( B_t \) be a Brownian motion. Fix a time \( t_0 \geq 0 \). Show that the process
\[
\{\tilde{B}_t = B_{t_0+t} - B_{t_0}, \ t \geq 0\}
\]
is a Brownian motion.

3.2 Let \( B_t \) be a two-dimensional Brownian motion. Given \( \rho > 0 \), compute:
\[
P(\|B_t\| < \rho).
\]

3.3 Let \( B_t \) be a \( n \)-dimensional Brownian motion. Consider an orthogonal \( n \times n \) matrix \( U \) (that is, \( UU' = I \)). Show that the process
\[
\tilde{B}_t = UB_t
\]
is a Brownian motion.

3.4 Compute the mean and autocovariance function of the geometric Brownian motion. Is it a Gaussian process?

3.5 Let \( B_t \) be a Brownian motion. Find the law of \( B_t \) conditioned by \( B_{t_1}, B_{t_2}, \) and \((B_{t_1}, B_{t_2})\) assuming \( t_1 < t < t_2 \).

3.6 Check if the following processes are martingales, where \( B_t \) is a Brownian motion:
\[
\begin{align*}
X_t &= B_t^3 - 3t B_t \\
X_t &= t^2 B_t - 2 \int_0^t sB_s ds \\
X_t &= e^{t/2} \cos B_t \\
X_t &= e^{t/2} \sin B_t \\
X_t &= (B_t + t) \exp(-B_t - \frac{1}{2}t) \\
X_t &= B_1(t)B_2(t).
\end{align*}
\]

63
In the last example, $B_1$ and $B_2$ are independent Brownian motions.

### 3.7 Find the stochastic integral representation on the time interval $[0, T]$ of the following random variables:

- $F = B_T$
- $F = B_T^2$
- $F = e^{B_T}$
- $F = \int_0^T B_t \, dt$
- $F = B_T^3$
- $F = \sin B_T$
- $F = \int_0^T t B_t^2 \, dt$

### 3.8 Let $p(t, x) = 1/\sqrt{1-t} \exp(-x^2/2(1-t))$, for $0 \leq t < 1$, $x \in \mathbb{R}$, and $p(1, x) = 0$. Define $M_t = p(t, B_t)$, where $\{B_t, 0 \leq t \leq 1\}$ is a Brownian motion.

a) Show that for each $0 \leq t < 1$, $M_t = M_0 + \int_0^t \frac{\partial p}{\partial x}(s, B_s) \, dB_s$.

b) Set $H_t = \frac{\partial p}{\partial x}(t, B_t)$. Show that $\int_0^1 H_t^2 \, dt < \infty$ almost surely, but $E(\int_0^1 H_t^2 \, dt) = \infty$.

### 4 Stochastic Differential Equations

Consider an $r$-dimensional Brownian motion $\{B_t, t \geq 0\}$ defined on a probability space $(\Omega, \mathcal{F}, P)$. Suppose that $\{\mathcal{F}_t, t \geq 0\}$ is a filtration such that $B_t$ is an $\mathcal{F}_t$-Brownian motion. We aim to solve stochastic differential equations of the form

$$dX_t = b(t, X_t) \, dt + \sigma(t, X_t) \, dB_t$$

with an initial condition $X_0$, which is a random variable independent of the Brownian motion $B_t$.

The coefficients $b_i(t, x)$, $1 \leq i \leq d$, $\sigma_{ij}(t, x)$, $1 \leq i \leq d$, $1 \leq j \leq r$, are Borel-measurable functions from $[0, T] \times \mathbb{R}^d$ into $\mathbb{R}$. Then, the vector $b(t, x)$ is called the drift coefficient, and the $d \times r$-matrix $\sigma(t, x)$ is called the dispersion matrix. In componentwise (25) is written as

$$dX_t^{(i)} = b_i(t, X_t) \, dt + \sum_{j=1}^r \sigma_{ij}(t, X_t) \, dB_t^j.$$

If the drift vanishes, then we have (25) is the ordinary differential equation:

$$\frac{dX_t}{dt} = b(t, X_t).$$
The stochastic differential equation (25) has the following heuristic interpretation. The increment $\Delta X_t = X_{t+\Delta t} - X_t$ can be approximatively decomposed into the sum of $b(t, X_t)\Delta t$ plus the term $\sigma(t, X_t)\Delta B_t$ which is interpreted as a random impulse. If $d = r = 1$, the approximate distribution of this increment will the the normal distribution with mean $b(t, X_t)\Delta t$ and variance $\sigma(t, X_t)^2\Delta t$.

A formal meaning of Equation (25) is obtained by rewriting it in integral form, using stochastic integrals:

$$X_t = X_0 + \int_0^t b(s, X_s)ds + \int_0^t \sigma(s, X_s)dB_s,$$

(26)

or equivalently

$$X_t^{(i)} = X_0^{(i)} + \int_0^t b_i(s, X_s)ds + \sum_{j=1}^r \int_0^t \sigma_{ij}(s, X_s)dB_s^j,$$

(27)

That is, the solution will be an Itô process $\{X_t, t \geq 0\}$. The solutions of stochastic differential equations are called diffusion processes.

The main result on the existence and uniqueness of solutions is the following.

**Theorem 31** Fix a time interval $[0, T]$. Suppose that the coefficients of Equation (27) satisfy the following Lipschitz and linear growth properties:

$$|b(t, x) - b(t, y)| + |\sigma(t, x) - \sigma(t, y)| \leq K|x - y|,$$

(28)

$$|b(t, x)|^2 + |\sigma(t, x)|^2 \leq K^2(1 + |x|^2),$$

(29)

for all $x, y \in \mathbb{R}^d$, $t \in [0, T]$, where $K$ is a positive constant. Suppose that $X_0$ is a random variable independent of the Brownian motion $\{B_t, 0 \leq t \leq T\}$ and such that $E(|X_0|^2) < \infty$. Then, there exists a unique continuous and adapted stochastic process $\{X_t, t \in [0, T]\}$ such that satisfies Equation (27). Moreover,

$$E(|X_t|^2) \leq C(1 + E(|X_0|^2))e^{Ct},$$

(30)

where the constant $C$ depends only on $T$ and $K$.

**Remarks:**

1.- For the uniqueness only a local Lipschitz property is required. On the other hand, the linear growth condition ensures that the solution does not explode in the time interval $[0, T]$. For example, the deterministic differential equation

$$\frac{dX_t}{dt} = X_t^2, \quad X_0 = 1, 0 \leq t \leq 1,$$

has the unique solution

$$X_t = \frac{1}{1 - t}, \quad 0 \leq t < 1,$$

which diverges at time $t = 1$. 

65
2. If the (local) Lipschitz property fails, then there might be more than one solution. For example, the deterministic differential equation

$$\frac{dX_t}{dt} = 3X_t^{2/3}, \quad X_0 = 0,$$

has infinitely many solutions because for each $a > 0$, the function

$$X_t = \begin{cases} 
0 & \text{if } t \leq a \\
(t - a)^3 & \text{if } t > a
\end{cases}$$

is a solution. In this example, the coefficient $b(x) = 3x^{2/3}$ does not satisfy the Lipschitz condition because the derivative of $b$ is not bounded.

3. The solution obtained in the previous theorem is strong, in the sense that it is adapted to the filtration generated by the Brownian motion.

Proof. Let us suppose that $X$ and $Y$ are two solutions. Define the stopping time $\tau_n = \inf\{t \geq 0 : \max(|X_t|, |Y_t|) \geq n\} \land T$. Clearly, $\lim_{n \to \infty} \tau_n = T$, and

$$X_{t \land \tau_n} - Y_{t \land \tau_n} = \int_0^{t \land \tau_n} (b(s,X_s) - b(s,Y_s)) \, ds + \int_0^{t \land \tau_n} (\sigma(s,X_s) - \sigma(s,Y_s)) \, dB_s.$$

Using the vector inequality $|v_1 + \cdots + v_k|^2 \leq k^2(|v_1|^2 + \cdots + |v_k|^2)$, the Hölder inequality for Lebesgue integrals, and the isometry property of the stochastic integral we may write

$$E\left(|X_{t \land \tau_n} - Y_{t \land \tau_n}|^2\right) \leq 2E\left[\left(\int_0^{t \land \tau_n} |b(s,X_s) - b(s,Y_s)| \, ds\right)^2\right]$$

$$+ 2E\left[\sum_{i=1}^d \left(\sum_{j=1}^r \int_0^{t \land \tau_n} (\sigma_{ij}(s,X_s) - \sigma_{ij}(s,Y_s)) \, dB_s^i\right)^2\right]$$

$$\leq 2tE\left[\int_0^{t \land \tau_n} |b(s,X_s) - b(s,Y_s)|^2 \, ds\right]$$

$$+ 2E\left[\int_0^{t \land \tau_n} |\sigma_{ij}(s,X_s) - \sigma_{ij}(s,Y_s)|^2 \, ds\right]$$

$$\leq 2(T + 1)K^2 \int_0^t E\left(|X_{s \land \tau_n} - Y_{s \land \tau_n}|^2\right) \, ds.$$

By Gronwall lemma we get $E\left(|X_{t \land \tau_n} - Y_{t \land \tau_n}|^2\right) = 0$ for all $t \in [0,T]$, and for all $n$. This allows to conclude the proof of the uniqueness.

To show the existence of solutions, consider the sequence of Picard approximations given by $X^{(0)}_t = X_0$, and

$$X^{(k+1)}_t = X_0 + \int_0^t b(s,X^{(k)}_s) \, ds + \int_0^t \sigma(s,X^{(k)}_s) \, dB_s,$$
for all $k \geq 0$. These processes are obviously continuous and adapted to the filtration generated by the Brownian motion. First we show that there exists a positive constant $C$ depending only on $T$ and $K$ such that
\[
E \left( |X_t^{(k)}|^2 \right) \leq C(1 + E(|X_0|^2))e^{Ct},
\]
for all $k \geq 0$. The proof of this estimate is easy. One we have this, we write
\[
X_t^{(k+1)} - X_t^{(k)} = M_t - V_t,
\]
where
\[
M_t = \int_0^t \left( \sigma(s, X_s^{(k)}) - \sigma(s, X_s^{(k-1)}) \right) dB_s,
\]
and
\[
V_t = \int_0^t \left( b(s, X_s^{(k)}) - b(s, X_s^{(k-1)}) \right) ds.
\]
The process $M$ is a square integrable martingale and
\[
E \left( \max_{0 \leq s \leq t} |M_s|^2 \right) \leq 4E \left( |M_t|^2 \right) = 4E \int_0^t \left| \sigma(s, X_s^{(k)}) - \sigma(s, X_s^{(k-1)}) \right|^2 ds
\]
\[
\leq 4K^2 \int_0^t \left| X_s^{(k)} - X_s^{(k-1)} \right|^2 ds.
\]
On the other hand,
\[
E \left( |V_t|^2 \right) \leq K^2 t E \int_0^t \left| X_s^{(k)} - X_s^{(k-1)} \right|^2 ds.
\]
Therefore
\[
E \left( \max_{0 \leq s \leq t} |X_s^{(k+1)} - X_s^{(k)}|^2 \right) \leq 2(T + 4)K^2 \int_0^t E \left( \left| X_s^{(k)} - X_s^{(k-1)} \right|^2 \right) ds.
\]
This inequality can be iterated to yield the successive upper bounds
\[
E \left( \max_{0 \leq s \leq t} \left| X_s^{(k+1)} - X_s^{(k)} \right|^2 \right) \leq C \frac{(Lt)^k}{k!},
\]
where $L = 2(T + 4)K^2$, and $C = \max_{0 \leq s \leq T} E \left( \left| X_s^{(1)} - X_0 \right|^2 \right) < \infty$. The Chebychev inequality now gives
\[
P \left( \max_{0 \leq s \leq t} \left| X_s^{(k+1)} - X_s^{(k)} \right| > \frac{1}{2^{k+1}} \right) \leq 2^{2(k+1)}C \frac{(LT)^k}{k!},
\]
and this upper bound is the general term of a convergent series. From Borel-Cantelli lemma, we conclude that there exists an event $G$ of probability one, and an integer-valued random variable $N(\omega)$ such that for every $\omega \in G$ and for all $k \geq N(\omega)$
\[
\max_{0 \leq s \leq t} |X_s^{(k+1)}(\omega) - X_s^{(k)}(\omega)| \leq \frac{1}{2^{k+1}}.
\]
Consequently,
\[
\max_{0 \leq s \leq t} |X_s^{(k+m)}(\omega) - X_s^{(k)}(\omega)| \leq \frac{1}{2k}
\]
for all \(k \geq N(\omega)\), and \(m \geq 1\). This implies that the sequence of sample paths \(\{X_t^{(k)}(\omega), 0 \leq t \leq T\}\) is convergent in the supremum norm in the space of continuous functions, from which follows the existence of a continuous limit \(\{X_t(\omega), 0 \leq t \leq T\}\) for all \(\omega \in G\). Then, the estimate (30) is a consequence of Fatou’s lemma. Finally, it suffices to show that the process \(X\) we have constructed satisfies Equation (27), and this follows easily from the properties of the Lebesgue and stochastic integrals. ■

4.1 Explicit solutions of stochastic differential equations

Itô’s formula allows us to find explicit solutions to some particular stochastic differential equations. Let us see some examples.

A) Linear equations. The geometric Brownian motion

\[
X_t = X_0 e^{(\mu - \frac{\sigma^2}{2})t + \sigma B_t}
\]
solves the linear stochastic differential equation

\[
dX_t = \mu X_t dt + \sigma X_t dB_t.
\]

More generally, the solution of the homogeneous linear stochastic differential equation

\[
dX_t = b(t) X_t dt + \sigma(t) X_t dB_t
\]

where \(b(t)\) and \(\sigma(t)\) are continuous functions, is

\[
X_t = X_0 \exp \left[ \int_0^t (b(s) - \frac{1}{2} \sigma^2(s)) \, ds + \int_0^t \sigma(s) dB_s \right].
\]

B) Ornstein-Uhlenbeck process. Consider the stochastic differential equation

\[
\begin{align*}
\frac{dX_t}{dt} &= a (m - X_t) dt + \sigma dB_t \\
X_0 &= x,
\end{align*}
\]

where \(a, \sigma > 0\) and \(m\) is a real number. This is a nonhomogeneous linear equation and to solve it we will make use of the method of variation of constants. The solution of the homogeneous equation

\[
\begin{align*}
\frac{dx_t}{dt} &= -ax_t dt \\
x_0 &= x
\end{align*}
\]
is \(x_t = xe^{-at}\). Then we make the change of variables \(X_t = Y_t e^{-at}\), that is, \(Y_t = X_t e^{at}\). The process \(Y_t\) satisfies

\[
\begin{align*}
\frac{dY_t}{dt} &= aX_t e^{at} dt + e^{at} dX_t \\
&= a\sigma e^{at} dt + \sigma e^{at} dB_t.
\end{align*}
\]
Thus,

\[ Y_t = x + m(e^{at} - 1) + \sigma \int_0^t e^{as} dB_s, \]

which implies

\[ X_t = m + (x - m)e^{-at} + \sigma e^{-at} \int_0^t e^{as} dB_s. \]

The stochastic process \( X_t \) is Gaussian. Its mean and covariance function are:

\[
E(X_t) = m + (x - m)e^{-at}, \\
\text{Cov}(X_t, X_s) = \sigma^2 e^{-a(t+s)} E\left( \left( \int_0^t e^{ar} dB_r \right) \left( \int_0^s e^{ar} dB_r \right) \right) \\
= \sigma^2 e^{-a(t+s)} \int_0^{t \wedge s} e^{2ar} dr \\
= \frac{\sigma^2}{2a} \left( e^{-a|t-s|} - e^{-a(t+s)} \right).
\]

The law of \( X_t \) is the normal distribution

\[ N(m + (x - m)e^{-at}, \frac{\sigma^2}{2a} (1 - e^{-2at}) \]

and it converges, as \( t \) tends to infinity to the normal law

\[ \nu = N(m, \frac{\sigma^2}{2a}). \]

This distribution is called invariant or stationary. Suppose that the initial condition \( X_0 \) has distribution \( \nu \), then, for each \( t > 0 \) the law of \( X_t \) will be also \( \nu \). In fact,

\[ X_t = m + (X_0 - m)e^{-at} + \sigma e^{-at} \int_0^t e^{as} dB_s \]

and, therefore

\[
E(X_t) = m + (E(X_0) - m)e^{-at} = m, \\
\text{Var}X_t = e^{-2at}\text{Var}X_0 + \sigma^2 e^{-2at} E\left( \left( \int_0^t e^{as} dB_s \right)^2 \right) = \frac{\sigma^2}{2a}.
\]

C) Consider the stochastic differential equation

\[ dX_t = f(t, X_t)dt + c(t)X_t dB_t, \quad X_0 = x, \quad (31) \]

where \( f(t, x) \) and \( c(t) \) are deterministic continuous functions, such that \( f \) satisfies the required Lipschitz and linear growth conditions in the variable \( x \). This equation can be solved by the following procedure:
a) Set \( X_t = F_t Y_t \), where

\[
F_t = \exp \left( \int_0^t c(s)dB_s - \frac{1}{2} \int_0^t c^2(s)ds \right),
\]

is a solution to Equation (31) if \( f = 0 \) and \( x = 1 \). Then \( Y_t = F_t^{-1} X_t \) satisfies

\[
dY_t = F_t^{-1} f(t, F_t Y_t) dt, \quad Y_0 = x.
\]

(32)

b) Equation (32) is an ordinary differential equation with random coefficients, which can be solved by the usual methods.

For instance, suppose that \( f(t, x) = f(t)x \). In that case, Equation (32) reads

\[
dY_t = f(t) Y_t dt,
\]

and

\[
Y_t = x \exp \left( \int_0^t f(s)ds \right).
\]

Hence,

\[
X_t = x \exp \left( \int_0^t f(s)ds + \int_0^t c(s)dB_s - \frac{1}{2} \int_0^t c^2(s)ds \right).
\]

D) General linear stochastic differential equations. Consider the equation

\[
dX_t = (a(t) + b(t) X_t) dt + (c(t) + d(t) X_t) dB_t,
\]

with initial condition \( X_0 = x \), where \( a, b, c \) and \( d \) are continuous functions.

Using the method of variation of constants, we propose a solution of the form

\[
X_t = U_t V_t
\]

(33)

where

\[
dU_t = b(t) U_t dt + d(t) U_t dB_t
\]

and

\[
dV_t = \alpha(t) dt + \beta(t) dB_t,
\]

with \( U_0 = 1 \) and \( V_0 = x \). We know that

\[
U_t = \exp \left( \int_0^t b(s)ds + \int_0^t d(s)dB_s - \frac{1}{2} \int_0^t d^2(s)ds \right).
\]

On the other hand, differentiating (33) yields

\[
a(t) = U_t \alpha(t) + \beta(t) d(t) U_t
\]

\[
c(t) = U_t \beta(t)
\]
that is,
\[ \beta(t) = c(t) U_t^{-1} \]
\[ \alpha(t) = [a(t) - c(t)d(t)] U_t^{-1}. \]

Finally,
\[ X_t = U_t \left( x + \int_0^t [a(s) - c(s)d(s)] U_s^{-1}ds + \int_0^t c(s) U_s^{-1}dB_s \right) \]

The stochastic differential equation
\[ X_t = X_0 + \int_0^t b(s, X_s)ds + \int_0^t \sigma(s, X_s)dB_s, \]
is written using the Itô’s stochastic integral, and it can be transformed into a stochastic differential equation in the Stratonovich sense, using the formula that relates both types of integrals. In this way we obtain
\[ X_t = X_0 + \int_0^t b(s, X_s)ds - \int_0^t \frac{1}{2} \sigma'(s, X_s)ds + \int_0^t \sigma(s, X_s) \circ dB_s, \]
because the Itô’s decomposition of the process \( \sigma(s, X_s) \) is
\[ \sigma(t, X_t) = \sigma(0, X_0) + \int_0^t \left( \sigma' b - \frac{1}{2} \sigma'' \sigma^2 \right) (s, X_s)ds + \int_0^t \sigma' \sigma (s, X_s)dB_s. \]

Yamada and Watanabe proved in 1971 that Lipschitz condition on the diffusion coefficient could be weakened in the following way. Suppose that the coefficients \( b \) and \( \sigma \) do not depend on time, the drift \( b \) is Lipschitz, and the diffusion coefficient \( \sigma \) satisfies the Hölder condition
\[ |\sigma(x) - \sigma(y)| \leq D|x - y|^\alpha, \]
where \( \alpha \geq \frac{1}{2} \). In that case, there exists a unique solution.

For example, the equation
\[ \left\{ \begin{array}{l}
         dX_t = |X_t|^r dB_t \\
         X_0 = 0
       \end{array} \right. \]
has a unique solution if \( r \geq 1/2 \).

**Example 1** The Cox-Ingersoll-Ross model for interest rates:
\[ dr(t) = a(b - r(t))dt + \sigma \sqrt{r(t)}dW_t. \]
4.2 Numerical approximations

Many stochastic differential equations cannot be solved explicitly. For this reason, it is convenient to develop numerical methods that provide approximated simulations of these equations.

Consider the stochastic differential equation
\[ dX_t = b(X_t)dt + \sigma(X_t)dB_t, \]  
with initial condition \( X_0 = x \).

Fix a time interval \([0, T]\) and consider the partition \( t_i = iT/n, \ i = 0, 1, \ldots, n \).

The length of each subinterval is \( \delta_n = T/n \).

Euler’s method consists in the following recursive scheme:
\[ X^{(n)}(t) = X^{(n)}(t_{i-1}) + b(X^{(n)}(t_{i-1}))\delta_n + \sigma(X^{(n)}(t_{i-1}))\Delta B_i, \]
\( i = 1, \ldots, n \), where \( \Delta B_i = B(t_i) - B(t_{i-1}) \). The initial value is \( X_0^{(n)} = x \). Inside the interval \((t_{i-1}, t_i)\) the value of the process \( X^{(n)} \) is obtained by linear interpolation.

The process \( X^{(n)} \) is a function of the Brownian motion and we can measure the error that we make if we replace \( X \) by \( X^{(n)} \):
\[ e_n = \sqrt{E[(X_T - X_T^{(n)})^2]}. \]

It holds that \( e_n \) is of the order \( \delta_n^{1/2} \), that is,
\[ e_n \leq c\delta_n^{1/2} \]
if \( n \geq n_0 \).

In order to simulate a trajectory of the solution using Euler’s method, it suffices to simulate the values of \( n \) independent random variables \( \xi_1, \ldots, \xi_n \) with distribution \( N(0, 1) \), and replace \( \Delta B_i \) by \( \sqrt{\delta_n} \xi_i \).

Euler’s method can be improved by adding a correction term. This leads to Milstein’s method. Let us explain how this correction is obtained.

The exact value of the increment of the solution between two consecutive points of the partition is
\[ X(t_i) = X(t_{i-1}) + \int_{t_{i-1}}^{t_i} b(X_s)ds + \int_{t_{i-1}}^{t_i} \sigma(X_s)dB_s. \]  

Euler’s method is based on the approximation of these exact values by
\[ \int_{t_{i-1}}^{t_i} b(X_s)ds \approx b(X(t_{i-1}))\delta_n, \]
\[ \int_{t_{i-1}}^{t_i} \sigma(X_s)dB_s \approx \sigma(X(t_{i-1}))\Delta B_i. \]
In Milstein’s method we apply Itô’s formula to the processes $b(X_s)$ and $\sigma(X_s)$ that appear in (35), in order to improve the approximation. In this way we obtain

$$X(t_i) - X(t_{i-1}) = \int_{t_{i-1}}^{t_i} \left[ b(X(t_{i-1})) + \int_{t_{i-1}}^{s} \left( bb' + \frac{1}{2} b'' \sigma^2 \right) (X_r) dr + \int_{t_{i-1}}^{s} (\sigma b') (X_r) dB_r \right] ds$$

$$+ \int_{t_{i-1}}^{t_i} \left[ \sigma(X(t_{i-1})) + \int_{t_{i-1}}^{s} \left( b\sigma' + \frac{1}{2} \sigma'' \sigma^2 \right) (X_r) dr + \int_{t_{i-1}}^{s} (\sigma \sigma') (X_r) dB_r \right] dB_s$$

$$= b(X(t_{i-1})) \delta_n + \sigma(X(t_{i-1})) \Delta B_i + R_i.$$

The dominant term is the residual $R_i$ is the double stochastic integral

$$\int_{t_{i-1}}^{t_i} \left( \int_{t_{i-1}}^{s} (\sigma \sigma') (X_r) dB_r \right) dB_s,$$

and one can show that the other terms are of lower order and can be neglected. This double stochastic integral can also be approximated by

$$(\sigma \sigma') (X(t_{i-1})) \int_{t_{i-1}}^{t_i} \left( \int_{t_{i-1}}^{s} dB_r \right) dB_s.$$

The rules of Itô stochastic calculus lead to

$$\int_{t_{i-1}}^{t_i} \left( \int_{t_{i-1}}^{s} dB_r \right) dB_s = \int_{t_{i-1}}^{t_i} (B_s - B_{t_{i-1}}) dB_s$$

$$= \frac{1}{2} \left( B_{t_i}^2 - B_{t_{i-1}}^2 \right) - B_{t_{i-1}} (B_{t_i} - B_{t_{i-1}}) - \delta_n$$

$$= \frac{1}{2} \left[ (\Delta B_i)^2 - \delta_n \right].$$

In conclusion, Milstein’s method consists in the following recursive scheme:

$$X^{(n)}(t_i) = X^{(n)}(t_{i-1}) + b(X^{(n)}(t_{i-1})) \delta_n + \sigma(X^{(n)}(t_{i-1})) \Delta B_i$$

$$+ \frac{1}{2} (\sigma \sigma') (X^{(n)}(t_{i-1})) \left[ (\Delta B_i)^2 - \delta_n \right].$$

One can show that the error $e_n$ is of order $\delta_n$, that is,

$$e_n \leq c \delta_n$$

if $n \geq n_0$. 

73
4.3 Markov property of diffusion processes

Consider an \( n \)-dimensional diffusion process \( \{X_t, t \geq 0\} \) which satisfies the stochastic differential equation

\[
dX_t = b(t, X_t)dt + \sigma(t, X_t)dB_t,
\]

where \( B \) is an \( m \)-dimensional Brownian motion and the coefficients \( b \) and \( \sigma \) are functions which satisfy the conditions of Theorem 31.

We will show that such a diffusion process satisfy the Markov property, which says that the future values of the process depend only on its present value, and not on the past values of the process (if the present value is known).

**Definition 32** We say that an \( n \)-dimensional stochastic process \( \{X_t, t \geq 0\} \) is a Markov process if for every \( s < t \) we have

\[
E(f(X_t)|X_r, r \leq s) = E(f(X_t)|X_s),
\]

for any bounded Borel function \( f \) on \( \mathbb{R}^n \).

In particular, property (37) says that for every Borel set \( C \in \mathcal{B}_{\mathbb{R}^n} \) we have

\[
P(X_t \in C|X_r, r \leq s) = P(X_t \in C|X_s).
\]

The probability law of Markov processes is described by the so-called transition probabilities:

\[
P(C, t, x, s) = P(X_t \in C|X_s = x),
\]

where \( 0 \leq s < t \), \( C \in \mathcal{B}_{\mathbb{R}^n} \) and \( x \in \mathbb{R}^n \). That is, \( P(\cdot, t, x, s) \) is the probability law of \( X_t \) conditioned by \( X_s = x \). If this conditional distribution has a density, we will denote it by \( p(y, t, x, s) \).

Therefore, the fact that \( X_t \) is a Markov process with transition probabilities \( P(\cdot, t, x, s) \), means that for all \( 0 \leq s < t \), \( C \in \mathcal{B}_{\mathbb{R}^n} \) we have

\[
P(X_t \in C|X_r, r \leq s) = P(C, t, X_s, s).
\]

For example, the real-valued Brownian motion \( B_t \) is a Markov process with transition probabilities given by

\[
p(y, t, x, s) = \frac{1}{\sqrt{2\pi(t-s)}} e^{-\frac{(x-y)^2}{2(t-s)}}.
\]

In fact,

\[
P(B_t \in C|\mathcal{F}_s) = P(B_t - B_s + B_s \in C|\mathcal{F}_s) = P(B_t - B_s + x \in C)|_{x=B_s},
\]

because \( B_t - B_s \) is independent of \( \mathcal{F}_s \). Hence, \( P(\cdot, t, x, s) \) is the normal distribution \( N(x, t-s) \).
We will denote by \( \{X^{s,x}_t, t \geq s\} \) the solution of the stochastic differential equation (36) on the time interval \([s, \infty)\) and with initial condition \(X^{s,x}_s = x\). If \(s = 0\), we will write \(X^{0,x}_t = X^x_t\).

One can show that there exists a continuous version (in all the parameters \(s, t, x\)) of the process \(\{X^{s,x}_t, 0 \leq s \leq t, x \in \mathbb{R}^n\}\).

On the other hand, for every \(0 \leq s \leq t\) we have the property:

\[
X^{x}_t = X^{x,x}_t
\]  

(38)

In fact, \(X^x_t\) for \(t \geq s\) satisfies the stochastic differential equation

\[
X^{x}_t = X^{x}_s + \int_s^t b(u, X^{x}_u)du + \int_s^t \sigma(u, X^{x}_u)dB_u.
\]

On the other hand, \(X^{s,y}_t\) satisfies

\[
X^{s,y}_t = y + \int_s^t b(u, X^{s,y}_u)du + \int_s^t \sigma(u, X^{s,y}_u)dB_u
\]

and substituting \(y\) by \(X^{x}_s\) we obtain that the processes \(X^x_t\) and \(X^{s,x}_t\) are solutions of the same equation on the time interval \([s, \infty)\) with initial condition \(X^{x}_s\). The uniqueness of solutions allow us to conclude.

**Theorem 33 (Markov property of diffusion processes)** Let \(f\) be a bounded Borel function on \(\mathbb{R}^n\). Then, for every \(0 \leq s < t\) we have

\[
E[f(X_t)|\mathcal{F}_s] = E[f(X^{s,x}_t)|x = X^{x}_s].
\]

**Proof.** Using (38) and the properties of conditional expectation we obtain

\[
E[f(X_t)|\mathcal{F}_s] = E[f(X^{s,x}_t)|\mathcal{F}_s] = E[f(X^{s,x}_t)|x = X^{x}_s],
\]

because the process \(\{X^{s,x}_t, t \geq s, x \in \mathbb{R}^n\}\) is independent of \(\mathcal{F}_s\) and the random variable \(X_s\) is \(\mathcal{F}_s\)-measurable.

This theorem says that diffusion processes possess the Markov property and their transition probabilities are given by

\[
P(C, t, x, s) = P(X^{s,x}_t \in C).
\]

Moreover, if a diffusion process is time homogeneous (that is, the coefficients do no depend on time), then the Markov property can be written as

\[
E[f(X_t)|\mathcal{F}_s] = E[f(X^{x}_t)|x = X^{x}_s].
\]

**Example 2** Let us compute the transition probabilities of the Ornstein-Uhlenbeck process. To do this we have to solve the stochastic differential equation

\[
dX_t = a(m - X_t)dt + \sigma dB_t
\]
in the time interval \([s, \infty)\) with initial condition \(x\). The solution is

\[
X^s_t = m + (x - m)e^{-a(t-s)} + \sigma e^{-at} \int_s^t e^{ar} dB_r
\]

and, therefore, \(P(\cdot, t, x, s) = \mathcal{L}(X^s_t)\) is a normal distribution with parameters

\[
\begin{align*}
E(X^s_t) &= m + (x - m)e^{-a(t-s)}, \\
\text{Var}X^s_t &= \sigma^2 e^{-2at} \int_s^t e^{2ar} dr = \frac{\sigma^2}{2a}(1 - e^{-2a(t-s)}).
\end{align*}
\]

### 4.4 Feynman-Kac Formula

Consider an \(n\)-dimensional diffusion process \(\{X_t, t \geq 0\}\) which satisfies the stochastic differential equation

\[
dX_t = b(t, X_t) dt + \sigma(t, X_t) dB_t,
\]

where \(B\) is an \(m\)-dimensional Brownian motion. Suppose that the coefficients \(b\) and \(\sigma\) satisfy the hypotheses of Theorem 31 and \(X_0 = x_0\) is constant.

We can associate to this diffusion process a second order differential operator, depending on time, that will be denoted by \(A_s\). This operator is called the generator of the diffusion process and it is given by

\[
A_s f(x) = \sum_{i=1}^n b_i(s, x) \frac{\partial f}{\partial x_i} + \frac{1}{2} \sum_{i,j=1}^n (\sigma \sigma^T)_{i,j}(s, x) \frac{\partial^2 f}{\partial x_i \partial x_j}.
\]

In this expression \(f\) is a function on \([0, \infty) \times \mathbb{R}^n\) of class \(C^{1,2}\). The matrix \((\sigma \sigma^T)(s, x)\) is the symmetric and nonnegative definite matrix given by

\[
(\sigma \sigma^T)_{i,j}(s, x) = \sum_{k=1}^n \sigma_{i,k}(s, x) \sigma_{j,k}(s, x).
\]

The relation between the operator \(A_s\) and the diffusion process comes from Itô’s formula: Let \(f(t, x)\) be a function of class \(C^{1,2}\), then, \(f(t, X_t)\) is an Itô process with differential

\[
\begin{align*}
&df(t, X_t) = \left( \frac{\partial f}{\partial t}(t, X_t) + A_t f(t, X_t) \right) dt \\
&\quad + \sum_{i=1}^n \sum_{j=1}^m \frac{\partial f}{\partial x_i}(t, X_t) \sigma_{i,j}(t, X_t) dB^j_t.
\end{align*}
\]

As a consequence, if

\[
E \left( \int_0^t \left| \frac{\partial f}{\partial x_i}(s, X_s) \sigma_{i,j}(s, X_s) \right|^2 ds \right) < \infty
\]

76
for every $t > 0$ and every $i, j$, then the process

$$M_t = f(t, X_t) - \int_0^t \left( \frac{\partial f}{\partial s} + A_s f \right) (s, X_s) ds$$  \hspace{1cm} (41)$$

is a martingale. A sufficient condition for (40) is that the partial derivatives $\frac{\partial f}{\partial x^i}$ have linear growth, that is,

$$\left| \frac{\partial f}{\partial x^i} (s, x) \right| \leq C(1 + |x|^N).$$  \hspace{1cm} (42)$$

In particular, if $f$ satisfies the equation $\frac{\partial f}{\partial t} + A_t f = 0$ and (42) holds, then $f(t, X_t)$ is a martingale.

The martingale property of this process leads to a probabilistic interpretation of the solution of a parabolic equation with fixed terminal value. Indeed, if the function $f(t, x)$ satisfies

$$\frac{\partial f}{\partial t} + A_t f = 0$$

\hspace{1cm} $f(T, x) = g(x)$  \hspace{1cm} \{ \}

in $[0, T] \times \mathbb{R}^n$, then

$$f(t, x) = E\left( g(X^{t,x}_T) \right)$$  \hspace{1cm} (43)$$

almost surely with respect to the law of $X_t$. In fact, the martingale property of the process $f(t, X_t)$ implies

$$f(t, X_t) = E(f(T, X_T)|X_t) = E(g(X_T)|X_t) = E(g(X^{t,x}_T)|x=X_t).$$

Consider a continuous function $q(x)$ bounded from below. Applying again Itô’s formula one can show that, if $f$ is of class $C^{1,2}$ and satisfies (42), then the process

$$M_t = e^{-\int_0^t q(X_s) ds} f(t, X_t) - \int_0^t e^{-\int_0^r q(X_s) ds} \left( \frac{\partial f}{\partial s} + A_s f - q f \right) (s, X_s) ds$$

is a martingale. In fact,

$$dM_t = e^{-\int_0^t q(X_s) ds} \sum_{i=1}^n \sum_{j=1}^m \frac{\partial f}{\partial x^i}(t, X_t) \sigma_{i,j}(t, X_t) dB^j_t.$$  \hspace{1cm} \{ \}

If the function $f$ satisfies the equation $\frac{\partial f}{\partial t} + A_t f - q f = 0$ then,

$$e^{-\int_0^t q(X_s) ds} f(t, X_t)$$  \hspace{1cm} (44)$$

will be a martingale.

Suppose that $f(t, x)$ satisfies

$$\frac{\partial f}{\partial t} + A_t f - q f = 0$$

\hspace{1cm} $f(T, x) = g(x)$  \hspace{1cm} \{ \}
on $[0, T] \times \mathbb{R}^n$. Then,

$$ f(t, x) = E \left( e^{-\int_t^T q(X_s^t, x) ds} g(X_T^t, x) \right). $$

(45)

In fact, the martingale property of the process (44) implies

$$ f(t, X_t) = E \left( e^{-\int_t^T q(X_s^t, x) ds} f(T, X_T)|\mathcal{F}_t \right). $$

Finally, Markov property yields

$$ E \left( e^{-\int_t^T q(X_s^t, x) ds} f(T, X_T)|\mathcal{F}_t \right) = E \left( e^{-\int_t^T q(X_s^t, x) ds} g(X_T^t, x) \right) |_{x=X_t}. $$

Formulas (43) and (45) are called the Feynman-Kac formulas.

**Exercises**

4.1 Show that the following processes satisfy the indicated stochastic differential equations:

(i) The process $X_t = \frac{B_t}{1+t}$ satisfies

$$ dX_t = -\frac{1}{1+t} X_t dt + \frac{1}{1+t} dB_t, $$

$X_0 = 0$

(ii) The process $X_t = \sin B_t$, with $B_0 = a \in (-\frac{\pi}{2}, \frac{\pi}{2})$ satisfies

$$ dX_t = -\frac{1}{2} X_t dt + \sqrt{1-X_t^2} dB_t, $$

for $t < T = \inf\{s > 0 : B_s \notin [-\frac{\pi}{2}, \frac{\pi}{2}] \}$.

(iii) The process $X_t = (x^{1/3} + \frac{1}{3} B_t)^3, x > 0$, satisfies

$$ dX_t = \frac{1}{3} X_t^{1/3} dt + X_t^{2/3} dB_t. $$

4.2 Consider an $n$-dimensional Brownian motion $B_t$ and constants $\alpha_i, i = 1, \ldots, n$. Solve the stochastic differential equation

$$ dX_t = rX_t dt + X_t \sum_{k=1}^n \alpha_k dB_k(t). $$

4.3 Solve the following stochastic differential equations:

$$ dX_t = r dt + \alpha X_t dB_t, \; X_0 = x $$

$$ dX_t = \frac{1}{X_t} dt + \alpha X_t dB_t, \; X_0 = x > 0 $$

$$ dX_t = X_t^\gamma dt + \alpha X_t dB_t, \; X_0 = x > 0. $$

For which values of the parameters $\alpha, \gamma$ the solution explodes?
4.4 The nonlinear stochastic differential equation

\[ dX_t = r X_t(K - X_t) dt + \beta X_t dB_t, \quad X_0 = x > 0 \]

is used to model the growth of population of size \( X_t \) in a random and crowded environment. The constant \( K > 0 \) is called the carrying capacity of the environment, the constant \( r \in \mathbb{R} \) is a measure of the quality of the environment and \( \beta \in \mathbb{R} \) is a measure of the size of the noise in the system. Show that the unique solution to this equation is given by

\[ X_t = \exp \left( \left( rK - \frac{1}{2} \beta^2 \right) t + \beta B_t \right) x - 1 + r \int_0^t \exp \left( \left( rK - \frac{1}{2} \beta^2 \right) s + \beta B_s \right) ds. \]

4.5 Find the generator of the following diffusion processes:

a) \( dX_t = \mu X_t dt + \sigma dB_t \), (Ornstein-Uhlenbeck process) \( \mu \) and \( r \) are constants

b) \( dX_t = r X_t dt + \alpha X_t dB_t \), (geometric Brownian motion) \( \alpha \) and \( r \) are constants

c) \( dX_t = r dt + \alpha X_t dB_t \), \( \alpha \) and \( r \) are constants

d) \( dY_t = \begin{bmatrix} \frac{dt}{dX_t} \\ dB_t \end{bmatrix} \) where \( X_t \) is the process introduced in a)

e) \( \begin{bmatrix} dX_1 \\ dX_2 \end{bmatrix} = \begin{bmatrix} 1 \\ X_2 \end{bmatrix} dt + \begin{bmatrix} 0 \\ e^{X_1} \end{bmatrix} dB_t \)

f) \( \begin{bmatrix} dX_1 \\ dX_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} dt + \begin{bmatrix} 1 & 0 \\ 0 & X_1 \end{bmatrix} \begin{bmatrix} dB_1 \\ dB_2 \end{bmatrix} \)

g) \( X(t) = (X_1, X_2, \ldots, X_n) \), where

\[ dX_k(t) = r_k X_k dt + X_k \sum_{j=1}^{n} \alpha_{kj} dB_j, \quad 1 \leq k \leq n \]

4.6 Find diffusion process whose generator are:

a) \( Af(x) = f'(x) + f''(x), \quad f \in C^2_0(\mathbb{R}) \)

b) \( Af(x) = \frac{\partial f}{\partial t} + cr \frac{\partial f}{\partial x} + \frac{1}{2} \alpha^2 x^2 \frac{\partial^2 f}{\partial x^2}, \quad f \in C^2_0(\mathbb{R}^2) \)

c) \( Af(x_1, x_2) = 2x_2 \frac{\partial f}{\partial x_2} + \log(1 + x_1^2 + x_2^2) \frac{\partial f}{\partial x_1} + \frac{1}{2} \left( 1 + x_1^2 \right) \frac{\partial^2 f}{\partial x_1^2} + x_1 \frac{\partial^2 f}{\partial x_1 \partial x_2} + \frac{1}{2} \frac{\partial^2 f}{\partial x_2^2}, \quad f \in C^2_0(\mathbb{R}^2). \)
